The information of the product number change

Starting April 1, 2001 the product number has been changed as listed below. To order, please use the new product number. For further information, please contact Epson sales representative.

Configuration of product number

●DEVICES (Example : S1F70000D00B100)

Introduction

This book describes SEIKO EPSON's full lineup of power supply ICs and includes a complete set of product specifications. Also included are sections on quality assurance and packaging.

We suggest that you use the selector guide beginning on the following page to choose the IC or IC series that most closely matches your application. Then you can

use the detailed product descriptions in subsequent sections to confirm device specifications and characteristics.

Please contact your local SEIKO EPSON sales representative for further information or assistance on these or other products.

Selection Guide

DC/DC Converter

Product	Features	Package
S1F76600M0B0	<ul style="list-style-type: none">Supply voltage conversion IC.It effectively converts input voltage V_{DD} into $-V_{DD}$ or $2V_{DD}$Output current : Max. 30mA at $-5V$Power conversion efficiency: Typ. 95%	SOP4-8pin

S1F76600 Series CMOS DC/DC Converter (Voltage Doubler)

DESCRIPTION

The S1F76600 Series is a highly efficient CMOS DC/DC converter for doubling an input voltage (from -1.5V to -8V). This power-saving IC allows portable computers and similar hand-held equipment to operate from a single power supply, even when they incorporate LSIs that operate at voltages different from those of logic circuits, for example, LCD drivers and analog LSIs.

The S1F76600C0B0 is available in 8-pin plastic DIPs, and the S1F76600M0B0, in 8-pin plastic SOPs.

FEATURES

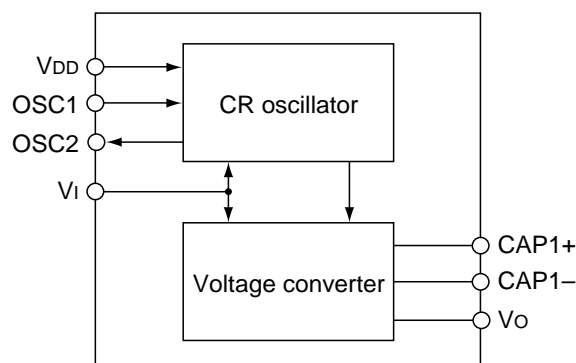

- 95% (Typ.) conversion efficiency
- Two output voltages, V_O , relative to V_{DD} and V_I
- 30mA maximum output current at 5V
- Connecting-in-series configuration obtains a higher output voltage ($V_I = -5\text{V}$, $V_O = -15\text{V}$ at two-in-series).
- Low operating voltage
- On-chip CR oscillator
- 8-pin plastic DIP and 8-pin plastic SOP

APPLICATIONS

- Fixed-voltage power supplies for battery-operated equipment
- Power supplies for pagers, memory cards, calculators and similar hand-held equipment

- Fixed-voltage power supplies for medical equipment
- Fixed-voltage power supplies for communications equipment
- Uninterruptable power supplies

FUNCTIONAL DESCRIPTIONS

CR Oscillator

S1F76600 has a built-in CR oscillator as the internal oscillator, and an external oscillation resistor R_{OSC} is connected between the pins OSC1 and OSC2 before operation.

Note 1

Since the oscillation frequency varies with wiring capacitance, make the cables between the terminals OSC1 and OSC2 and R_{OSC} as short as possible.

When setting the external resistor R_{OSC} , find R_{OSC} suitable for f_{OSC} that brings about the maximum efficiency from characteristics graph (9) and (10). The relations between R_{OSC} and f_{OSC} in characteristics graph (1) are expressed approximately with the following formula as

far as the straight portion ($500k\Omega < R_{OSC} < 2M\Omega$) is concerned:

$$R_{OSC} = A \cdot (1/f_{OSC})$$

(A : Constant, When GND is 0V and V_{DD} is 5V, A is approximately 2.0×10^{10} (I/F).)

So, the R_{OSC} value can be obtained from this formula. (Recommended oscillation frequency : 10kHz to 30kHz (R_{OSC} : $2M\Omega$ to $680k\Omega$))

When the external clock operates, make the pin OSC2 open as shown below and input the 50% duty of the external clock from the pin OSC1.

Voltage Multiplier

The voltage multiplier uses the clock signal from the oscillator to double the input voltage. This requires two external capacitors—a charge-pump capacitor, C1, between CAP1+ and CAP1-, and a smoothing capacitor, C2, between V_I and V_O .

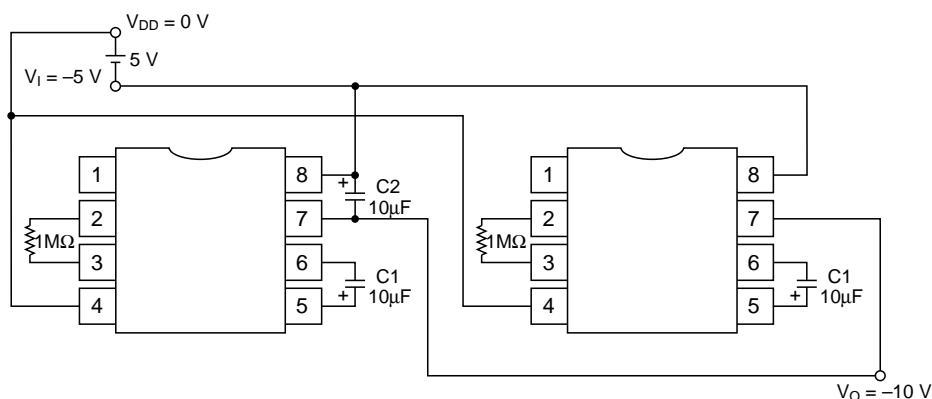

Doubled potential levels

TYPICAL APPLICATIONS

Parallel Connection

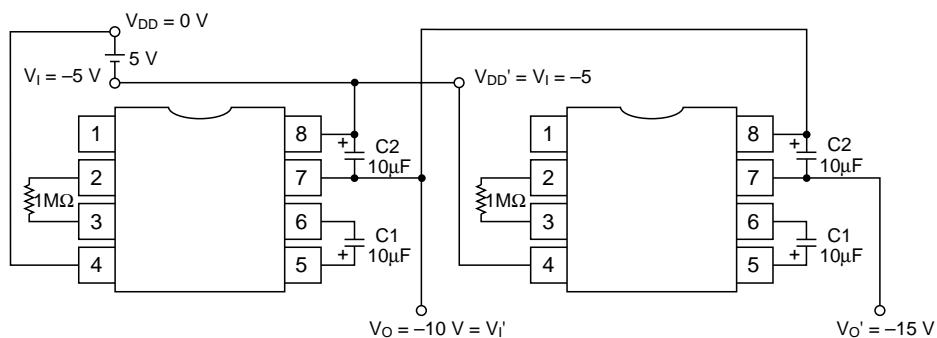

Connecting two or more chips in parallel reduces the output impedance by $1/n$, where n is the number of devices used.

Serial Connection

Connecting two or more chips in series obtains a higher output voltage than can be obtained using a parallel

connection, however, this also raises the output impedance.

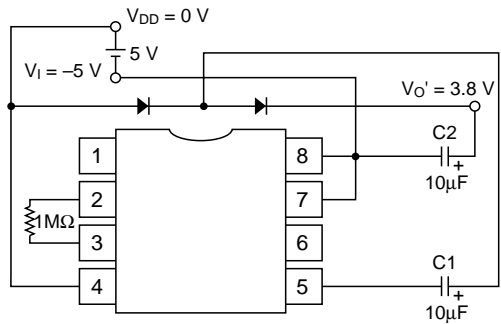

Potential levels

Positive Voltage Conversion

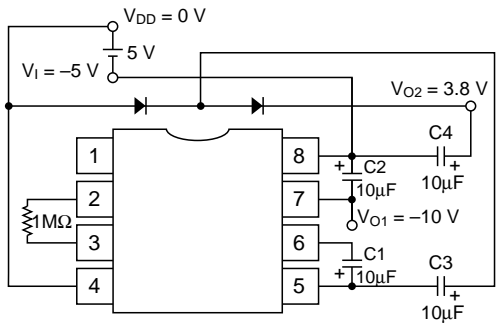

Diodes can be added to a circuit connected in parallel to make a negative voltage positive.

Simultaneous Voltage Conversion

Combining a multipler circuit with a positive voltage conversion circuit generates both -10 V and 3.8 V outputs from a single input.

Potential levels

S1F76620 Series CMOS DC/DC Converter (Voltage Doubler)

DESCRIPTION

S1F76620 is a high efficiency and low power consumption CMOS DC/DC converter. It enables to obtain 2 times step-up output (3.0 to 16V) from input voltage (1.5 to 8V). Also, S1F76620 enable to drive ICs (liquid crystal driver, analog IC, etc.), which require another power supply in addition to logic main power supply, with a single power supply, and it is suitable for micro power IC of hand-held computers, handy devices, etc. due to its small power consumption.

FEATURES

- (1) High efficiency and low power consumption CMOS DC/DC converter
- (2) Easy voltage conversion from input voltage V_{DD} (5V) to positive potential side or negative potential side
 - Input V_{DD} (5V) to output $-V_{DD}$ (-5V), $2V_{DD}$ (10V)
- (3) Output current : Max. 30mA ($V_{DD} = 5V$)
- (4) Power conversion efficiency : Typ. 95%
- (5) Possibility of series connection
(In 2-piece use, $V_{DD} = 5V$, $V_O = 15V$)
- (6) Low voltage operation : Suitable for battery drive
- (7) Built-in CR oscillator
- (8) SOP4-8pin S1F76620M0A0
Bare Chip S1F76620D0A0

FUNCTIONAL DESCRIPTIONS

CR Oscillator

S1F76620 has a built-in CR oscillator as the internal oscillator, and an external oscillation resistor ROSC is connected between the pins OSC1 and OSC2 before operation.

Note 1

Since the oscillation frequency varies with wiring capacitance, make the cables between the terminals OSC1 and OSC2 and ROSC as short as possible.

When setting the external resistor ROSC, find ROSC suitable for fOSC that brings about the maximum efficiency from characteristics graph (9) and (10). The relations between ROSC and fOSC in characteristics graph (1) are expressed approximately with the following formula as far as the straight portion ($500\text{k}\Omega < \text{ROSC} < 2\text{M}\Omega$) is concerned:

$$\text{ROSC} = A \cdot (1/\text{fOSC})$$

(A : Constant, When GND is 0V and VDD is 5V, A is approximately 2.0×10^{10} (I/F).)

So, the ROSC value can be obtained from this formula.
(Recommended oscillation frequency : 10kHz to 30kHz
(ROSC : $2\text{M}\Omega$ to $680\text{k}\Omega$))

When the external clock operates, make the pin OSC2 open as shown below and input the 50% duty of the external clock from the pin OSC1.

Voltage Conversion Circuit

The voltage conversion circuit uses clocks generated in the CR oscillator to double the input supply voltage VDD.

In case of 2 times step-up, 2 times voltage ($2V_{\text{DD}}$) of the input voltage is obtained from the VO pin when a pump up capacitor is connected between CAP1+ and CAP2- and a smoothing capacitor is connected between VDD and VO outside.

When GND is 0 and VDD is 5, the relations between input/output and voltage are as shown below:

ELECTRICAL CHARACTERISTICS**Absolute Maximum Ratings**

(Ta = -40 to +85°C)

Parameter	Symbol	Rating		Unit	Remarks
		Min.	Max.		
Input supply voltage	V _{IN}	-0.5	10.0	V	—
Input pin voltage	V _I	-0.5	V _{DD} + 0.5	V	OSC1, OSC2
Output voltage	V _O	—	20	V	—
Output supply voltage	V _{CAP+}	-0.5	V _{DD} + 0.5	V	CAP+
Output pin voltage	V _{CAP-}	-0.5	V _O + 0.5	V	CAP-
Allowable loss	P _D	—	300	mW	DIP-8pin
			150		SOP-8pin
Operating temperature	T _{opr}	-40	85	°C	—
Storage temperature	T _{stg}	-65	150	°C	—

Note 1

Under the conditions exceeding the above absolute maximum ratings, the IC may result in a permanent destruction. An operation for a long period under the conditions of the above absolute maximum ratings may deteriorate the reliability remarkably.

Note 2

All voltage values are based on GND being 0V.

Recommended Operating Conditions

EXAMPLE OF REFERENCE EXTERNAL CONNECTION

2 Times Step-up

2 times step-up output of V_O ($2 \times V_{DD}$) is obtained from the circuit shown in Figure 1.

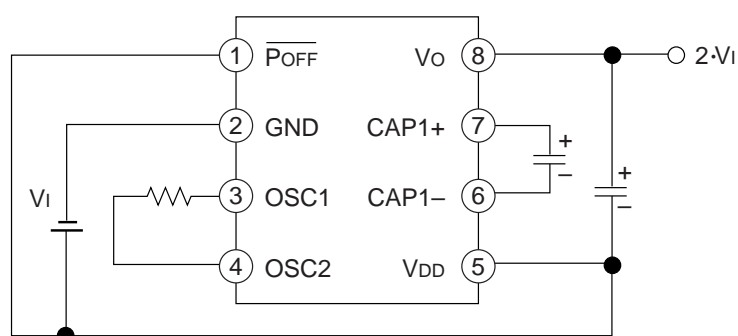

Figure 1 2 Time Step-up Operation

Parallel Connection

It is possible to make the output impedance (R_O) small when several pieces of the circuit shown in Figure 1 are connected. Parallel connection of n circuits reduces R_O to $1/n$ approximately. One piece of the smoothing capacitor C_2 can be commonly used.

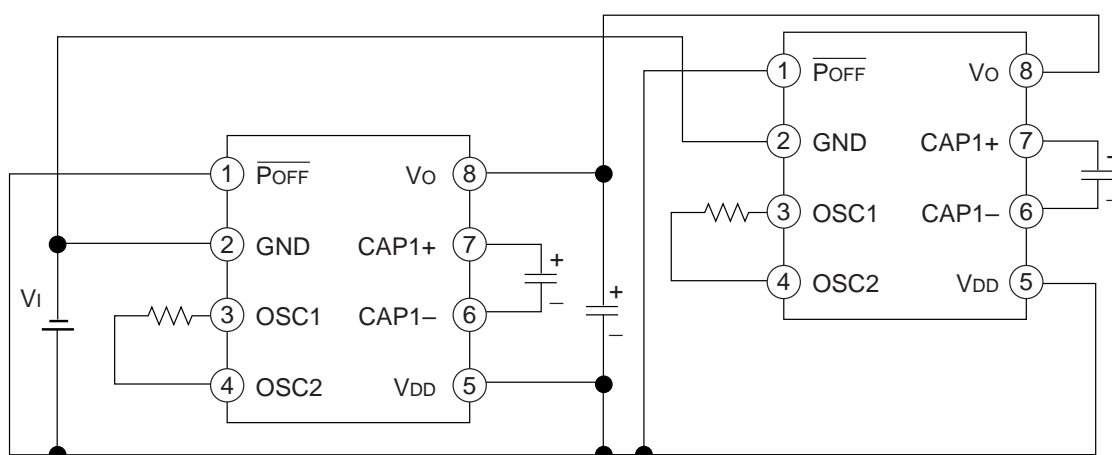

Figure 2 Parallel Connection

Series Connection

When S1F76620 is connected in series (VDD and VO in the previous stage are connected to GND and VDD in the next stage respectively), the output voltage can be increased more. But the series connection makes the output impedance high. Figure 3 shows an example of the series connection to get $V_O = 15V$ from $V_{DD} = 5V$.

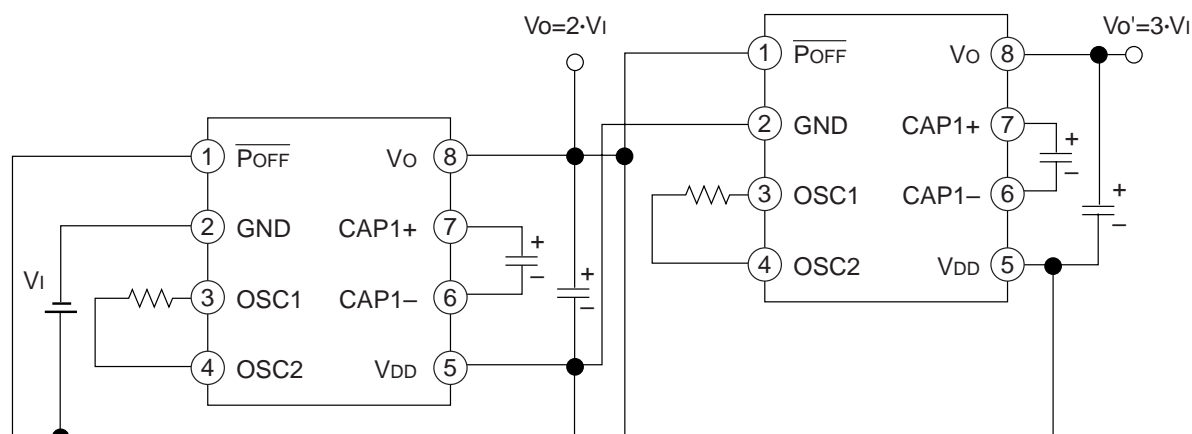

Figure 3 Series Connection

Figure 4 Power Supply Relations in Series Connection (1)

Note

When the input voltage in the next stage is as per the specification ($V_{DD}-GND \leq 8V$) in a series connection, the output in the first stage (V_O-V_{DD}) can be used as the input in the next stage ($V_{DD}-GND$). (See Figure 5.)

Figure 5 Power Supply Relations in Series Connection (2)

Negative Voltage Conversion

S1F76620 can boost input voltage to twice on the positive potential side by using the circuit shown in Figure 6. But the output voltage drops by the forward voltage V_F of the diode. When GND is 0V, V_{DD} is 5V and V_F is 0.6V as shown in Figure 6 for example, V_O is calculated as follows: $V_O = -5V + 2 \times 0.6V = -3.8V$.

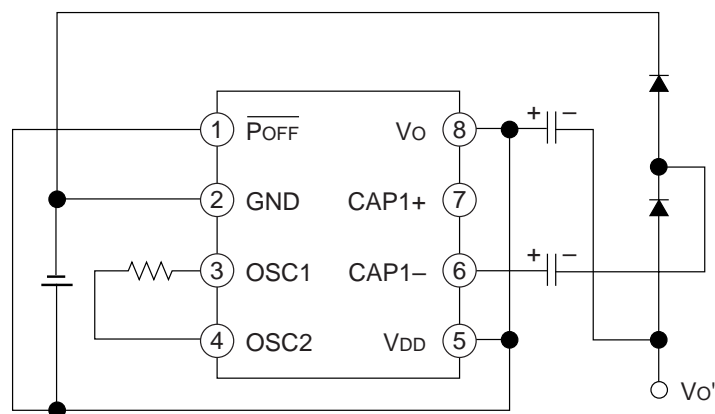

Figure 6 Negative Voltage Conversion

Negative Voltage Conversion + Positive Voltage Conversion

When the 3 times step-up operation shown in Figure 1 and the positive voltage conversion in Figure 6 are combined, the circuit shown in Figure 7 can be formed and 10V and $-3.8V$ can be obtained from the input 5V. However, the output impedance is higher than in case of connection of either one only (the negative voltage conversion or the positive voltage conversion).

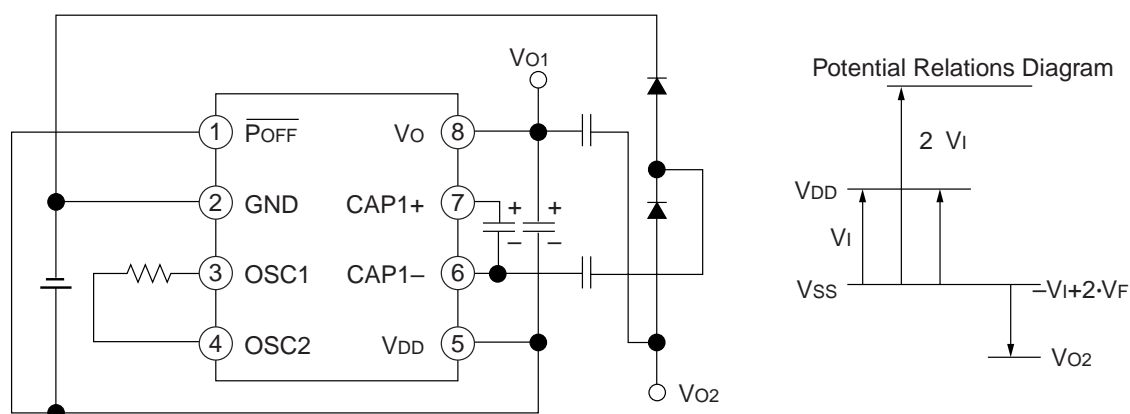

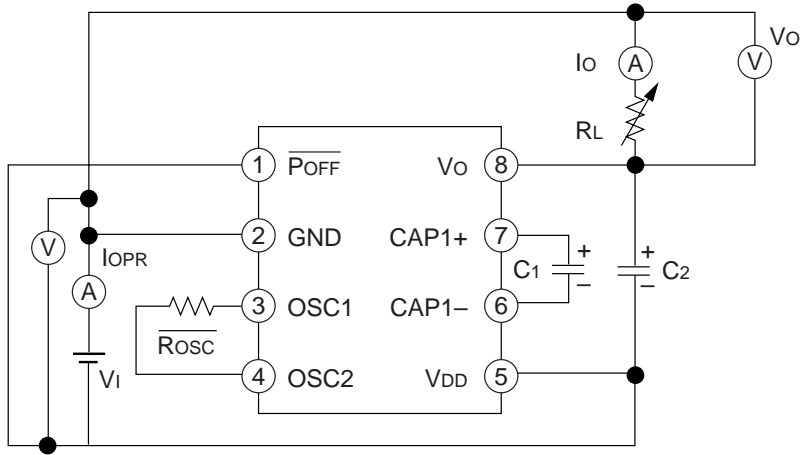

Figure 7 Negative Voltage Conversion + Positive Voltage Conversion

2. DC/DC Converter & Voltage Regulator

S1F76610 Series CMOS DC/DC Converter (Voltage Doubler / Tripler) & Voltage Regulator

DESCRIPTION

The S1F76610 Series is a highly efficient CMOS DC/DC converter for doubling or tripling an input voltage. It incorporates an on-chip voltage regulator to ensure stable output at the specified voltage. The S1F76610 Series offers a choice of three, optional temperature gradients for applications such as LCD panel power supplies.

The S1F76610C0B0 is available in 14-pin plastic DIPs, the S1F76610M0B0, in 14-pin plastic SOPs, and the S1F76610M2B0 in 16-pin plastic SSOPs.

FEATURES

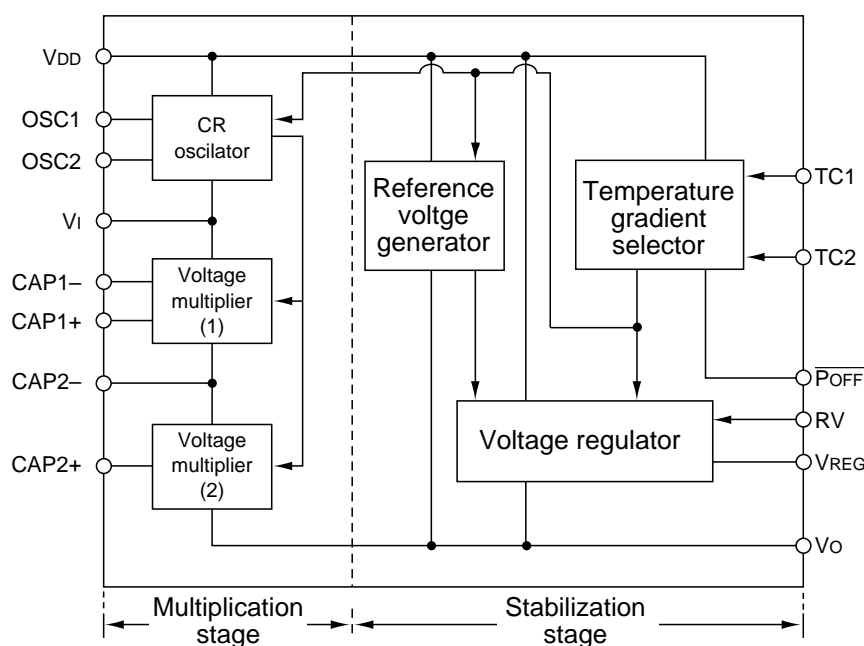

- 95% (Typ.) conversion efficiency
- Up to four output voltages, V_O , relative to the input voltage, V_I
- On-chip voltage regulator
- 20mA maximum output current at $V_I = -5V$
- Three temperature gradients : -0.1 , -0.4 and $-0.6/^{\circ}C$

- External shut-down control
- 2 μA maximum output current when shut-down
- Two-in-series configuration doubles negative output voltage.
- On-chip RC oscillator
- S1F76610C0B0 Plastic DIP-14 pin
- S1F76610M0B0 Plastic SOP5-14 Pin
- S1F76610M2B0 Plastic SSOP2-16 pin

APPLICATIONS

- Power supplies for LCD panels
- Fixed-voltage power supplies for battery-operated equipment
- Power supplies for pagers, memory cards, calculators and similar hand-held equipment
- Fixed-voltage power supplies for medical equipment
- Fixed-voltage power supplies for communications equipment
- Power supplies for microcomputers
- Uninterruptable power supplies

Soldering temperature and time	T_{sol}	$260 \cdot 10$	$^{\circ}\text{C} \cdot \text{s}$	At leads

Notes

- Using the IC under conditions exceeding the aforementioned absolute maximum ratings may lead to permanent destruction of the IC. Also, if an IC is operated at the absolute maximum ratings for a longer period of time, its functional reliability may be substantially deteriorated.
- All the voltage ratings are based on $V_{DD} = 0\text{V}$.
- The output terminals (V_O, V_{REG}) are meant to output boosted voltage or stabilized boosted voltage. They, therefore, are not the terminals to apply an external voltage. In case the using specifications unavoidably call for application of an external voltage, keep such voltage below the voltage ratings given above.

Recommended Operating Conditions

$V_{DD} = 0\text{V}$, $T_a = -40$ to $+85^{\circ}\text{C}$ unless otherwise noted

Parameter	Symbol	Conditions	Rating			Unit
			Min.	Typ.	Max.	
Oscillator startup voltage	V_{STA}	$R_{OSC} = 1\text{M}\Omega$ $C_3 = 10\ \mu\text{F}$, $C_1/C_3 \leq 1/20$, $T_a = -20$ to $+85^{\circ}\text{C}$. See note 1.	—	—	-1.8	V
		$R_{OSC} = 1\text{M}\Omega$	—	—	-2.2

Temperature Gradient Control

The S1F7661C0B0 offers a choice of three temperature gradients which can be used to adjust the voltage regulator output in applications such as power supplies for driving LCDs.

$\overline{\text{PoFF}}$	TC2	TC1	Temperature gradient (%/°C) See note 2.	Voltage regulator output	CR oscillator	Remarks
See note 1.						
1 (VDD)	Low (Vo)	Low (Vo)	-0.4	ON	ON	
1 (VDD)	Low (Vo)	High (VDD)	-0.1	ON	ON	
1 (VDD)	High (VDD)	Low (Vo)	-0.6	ON	ON	
1 (VDD)	High (VDD)	High (VDD)	-0.6	ON	OFF	Serial connection
0 (Vi)	Low (Vo)	Low (Vo)	—	OFF (high impedance)	OFF	
0 (Vi)	Low (Vo)	High (VDD)	—	OFF (high impedance)	OFF	
0 (Vi)	High (VDD)	Low (Vo)	—	OFF (high impedance)	OFF	
0 (Vi)	High (VDD)	High (VDD)	—	OFF (high impedance)	OFF	Multiplier operational

Notes

- The definition of LOW for $\overline{\text{PoFF}}$ differs from that for TC1 and TC2.
- The temperature gradient affects the voltage between VDD and VREG.

FUNCTIONAL DESCRIPTIONS

CR Oscillator

The on-chip CR oscillator network frequency is determined by the external resistor, R_{OSC} , connected between OSC1 and OSC2. This oscillator can be disabled in favor of an external clock by leaving OSC2 open and applying an external clock signal to OSC1.

Reference Voltage Generator and Voltage Regulator

The reference voltage generator supplies a reference voltage to the voltage regulator to control the output. This voltage can be switched ON and OFF.

Voltage Multiplier

The voltage multiplier uses the clock signal from the oscillator to double or triple the input voltage. This requires three external capacitors—two charge-pump capacitors between CAP1+ and CAP1- and CAP2+ and CAP2-, respectively, and a smoothing capacitor between V_I and V_O .

Double voltage potential levels

Tripled voltage potential levels

S1F76610 Series

TYPICAL APPLICATIONS

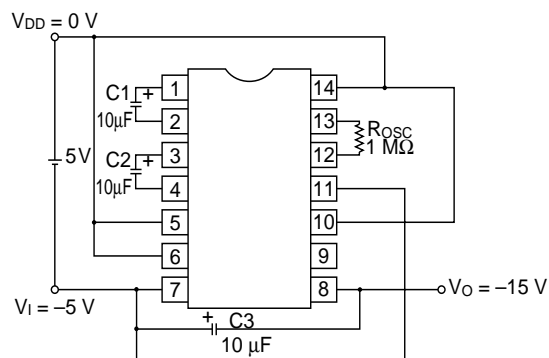

Voltage Tripler with Regulator

The following figure shows the circuit required to triple the input voltage, regulate the result and add a temperature gradient of $-0.4\%/^{\circ}\text{C}$. Note that the high input impedance of RV requires appropriate noise countermeasures.

Converting a Voltage Tripler to a Voltage Doubler

To convert this circuit to a voltage doubler, remove capacitor C2 and short circuit CAP2- to VO.

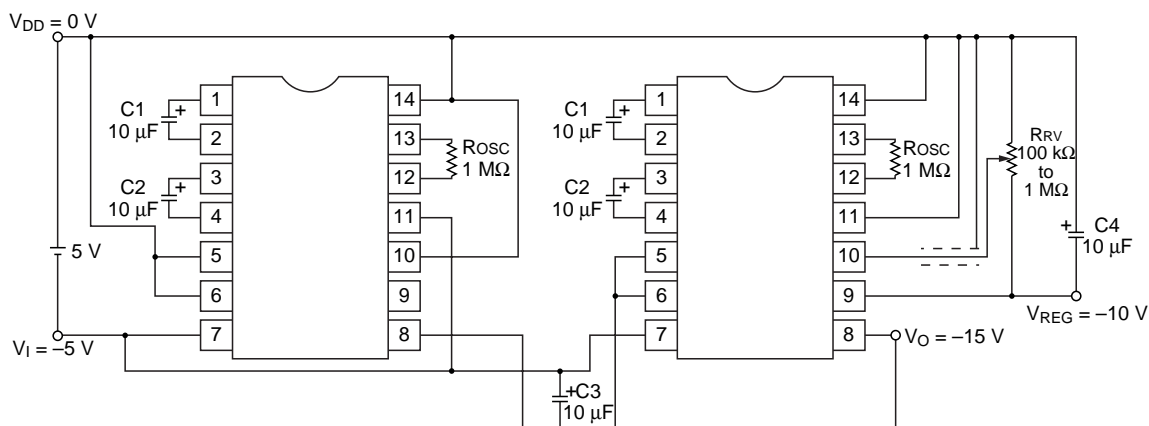

Parallel Connection

Connecting two or more chips in parallel reduces the output impedance by $1/n$, where n is the number of devices used.

Only the single output smoothing capacitor, C3, is re-

quired when any number of devices are connected in parallel. Also, the voltage regulator in one chip is sufficient to regulate the combined output.

Serial Connection

Connecting two or more chips in series obtains a higher output voltage than can be obtained using a parallel

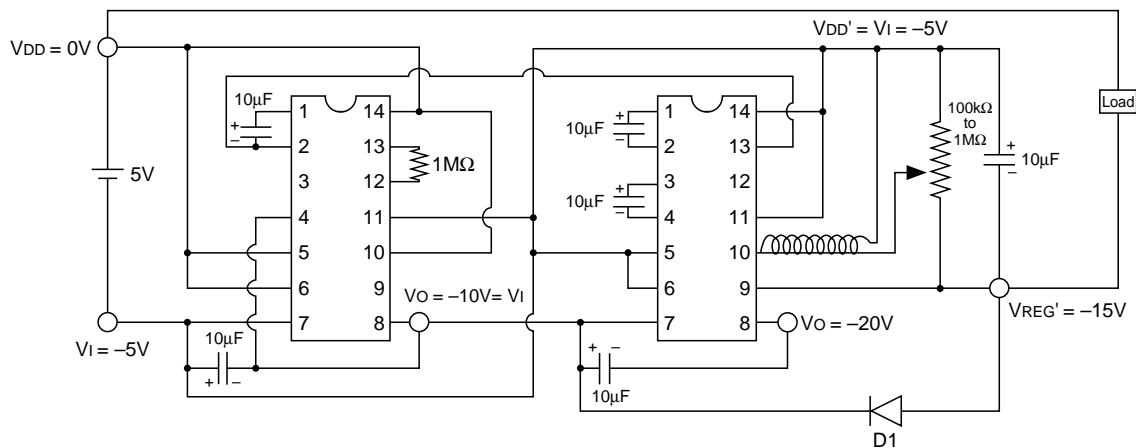

connection, however, this also raises the output impedance.

<Precautions when connecting loads>

In case of series connections, when connecting loads between the first stage VDD (or other potential of the second stage VDD or up) and the second stage VREG as shown in Fig. 2-13, be cautious about the following point.

- * When normal output is not occurring at the VREG terminal such as at times of starting up or when turning the VREG off by POF signals, if current flows into the second stage VREG terminal through the load from

the first stage VDD (or other potential of the second stage VDD or up) to cause a voltage exceeding the absolute maximum rating for the second stage VDD at the VREG terminal, normal operation of the IC may be hampered. Consequently, When making a series connection, insert a diode D1 between the second stage VI and VREG as shown in Fig. 2-13 so that a voltage exceeding the second stage VDD or up may not be applied to the VREG terminal.

Positive Voltage Conversion

Adding diodes converts a negative voltage to a positive one.

To convert the voltage tripler shown earlier to a voltage doubler, remove C2 and D2, and short circuit D3. Small Schottky diodes are recommended for all these diodes. The resulting voltage is lowered by V_F , the voltage drop in the forward direction for each diode used. For example, if $V_{DD} = 0V$, $V_I = -5V$, and $V_F = 0.6V$, the resulting voltages would be as follows.

- For a voltage tripler,
 $V_O = 10 - (3 \times 0.6) = 8.2V$
- For a voltage doubler,
 $V_O = 5 - (2 \times 0.6) = 3.8V$

Simultaneous Voltage Conversion

Combining a standard voltage tripler circuit with one for positive voltage conversion generates both -15 and 8.2V outputs from a single input, however, it also raises the output impedance.
A voltage doubler generates -10 and 3.8V outputs.

Using an External Gradient

The S1F7661C0B0/M0B0 offers three built-in temperature gradients— -0.1 , -0.4 and $-0.6\%/^{\circ}\text{C}$. To set the gradient externally, place a thermistor, R_T , in series with the variable resistor, R_{RV} , used to adjust the output voltage.

Potential levels

S1F76540 Series Charge Pumping DC/DC Converter & Voltage Regulator

DESCRIPTION

The S1F76540C0A0/M0A0 is a CMOS process, charge-pumping DC/DC converter and voltage regulator featuring the very high efficiency but low power consumption. An addition of four, three, or two external capacitors can generate four-, three- or two-time output voltage in negative direction than the input voltage. Also, the built-in voltage regulator can set any output voltage of DC/DC converter and can output the regulated voltage using two external resistances. As the regulator output can have a negative temperature gradient that is required for LCD panels, it is optimum for the LCD panel power supply.

FEATURES

- Charge-pumping, DC-to-DC converter (four-, three- or two-time negative boosting)
- Built-in voltage regulator (regulated voltage output circuit)
- High power conversion efficiency : 95%
- Low current consumption : 130 μ A ($V_I = -5.0$ V during four-time boosting, Typ.)
- High output capacity : 20 mA (Max.)

- Input voltages : -2.4 to -5.5 V (during four-time boosting)
: 2.4 to -7.3 V (during three-time boosting)
: 2.4 to -11 V (during two-time boosting)
- DC/DC converter output voltage : $|\text{Input voltage}| \times 4$ (Max.)
- Built-in reference voltage for high-precision regulator : 1.5 ± 0.05 V (at C_{T0})
- Temperature gradient function of regulator output voltages : -0.04 , -0.15 , -0.35 , -0.55 (%/ $^{\circ}$ C)
- Low standby current (during power-off) : 5.0 μ A
- Power-off by the external signal
- Full built-in oscillator circuit
- Lineup : S1F76540M0A0, 16-pin SSOP
: S1F76540C0A0, 16-pin DIP

APPLICATIONS

- Power supply of medium- and small-capacity LCD panels
- Regulated power supply of battery driven devices

Output current	I _O		N ≤ 4: 20 N > 4: 80/N	mA	N = Boost time V _O and V _{REG} pins
Allowable loss	P _D		210	mW	T _a ≤ 25°C
Operating temperature	T _{opr}	−30	85	°C	
Storage temperature	T _{stg}	−55	150	°C	
Soldering temperature and time	T _{sol}		260 • 10	°C • s	At leads

Notes: 1. An operation exceeding the above absolute maximum ratings may cause a malfunction or permanent damage of devices. The device reliability may drop excessively even if the devices temporarily operate normally.

2. Electrical potential to peripheral systems:

The S1F76540 common power supply has the highest potential (V_{DD}). The electrical potential given by this specification is based on V_{DD} = 0 V. Take care to avoid a potential problem during connection to a peripheral system.

FUNCTIONAL DESCRIPTIONS

Clock Generator Circuit

As the S1F76540 has a built-in clock generator circuit, no more parts are required for voltage boost control. The clock frequency changes according to the FC pin voltage level as defined on Table 2.5. Low Output mode or High Output mode is selectable. This allows frequency selection according to the used capacitance and

load current as the boost output impedance changes depending on the clock frequency and external booster capacitance. However, the High Output mode has the current consumption approximately four times larger than the Low Output mode.

Table 2.5 FC pin setup

FC pin	Mode	Clock frequency	Characteristics			
			Current consumption	Output ripple	Output impedance	Capacitance
High (V _{DD})	Low Output	4.0 kHz (Typ.)	I _{OP} (*1)	V _{RR} (*2)	See Figure A1.	See Figure A1.
Low (V _I)	High Output	16.0 kHz (Typ.)	I _{OP} × Approx. 4	V _{RI} × Approx. 1/4	See Figure A1.	See Figure A1.

*1 See the DC characteristics table for current consumption.

*2 See Section Page 2-32 for the output ripple definition and calculation.

Figure A1 Characteristic chart: Capacitance vs. output impedance when 4X pressure is applied
NOTE: This characteristic chart simply indicates an approximate trend in the characteristics, which may vary depending on evaluation environment, parts used, and other factors.

Voltage Converter

The voltage converter, consisting of a boost control circuit and a voltage converter circuit, receives clocks from the clock generator circuit and boosts the input power voltage (V_I) four, three or two times. During four-time boosting, however, the three-time and two-

time boost outputs cannot be obtained simultaneously. Figure 2.4 gives the potential relationship during four-, three- and two-time boosting. The C2P pin is also used as the master clock output during parallel connection.

Figure 2.4 Electrical potentials during boosting (at $-5V$ input)

Caution:

- When connecting a capacitor to the C1P, C2P, C1N, C2N, C3N, or V_O pin for voltage conversion, close the capacitor to the IC package as much as possible to minimize the wiring length.

Reference Voltage Circuit

The S1F76540 has a built-in reference voltage circuit for voltage regulation. The regulated voltage (explained in the next “voltage regulator circuit” section) is set depending on the division ratio between this refer-

ence voltage and the external resistance. The reference voltage can be used to change the temperature coefficient at pins TC1 and TC2. One of four states can be selected as listed on Table 2.6.

Table 2.6 Setup of reference voltage and temperature coefficient

Mode	TC1 (High = V _{DD}) (Low = V _I)	TC2 (High = V _{DD}) (Low = V _I)	Reference voltage, V _{REF} (V)			Temperature coefficient, C _T (%/°C)		
			Min.	Typ.	Max.	Min.	Typ.	Max.
CT0	High	High	−1.55	−1.5	−1.45	−0.07	−0.04	0
CT1	High	Low	−1.70	−1.5	−1.30	−0.25	−0.15	−0.07
CT2	Low	High	−1.90	−1.5	−1.10	−0.45	−0.35	−0.20
CT3	Low	Low	−2.15	−1.5	−0.85	−0.75	−0.55	−0.30

Notes: 1. The reference voltage is given at T_a = 25°C.

2. The reference voltage and temperature coefficient of the chip products may vary depending on the moldings used on each chip. Use these chips only after the temperature test.

The temperature coefficient (C_T) is defined by the following equation. The negative sign of the temperature coefficient (C_T) means that the |V_{REF}| value decreases when the temperature rises.

$$C_T = \frac{|V_{REF}(50^\circ\text{C})| - |V_{REF}(0^\circ\text{C})|}{50^\circ\text{C} - 0^\circ\text{C}} \times \frac{100}{|V_{REF}(25^\circ\text{C})|}$$

Notes on TC1 and TC2 pin replacement:

- When replacing the TC1 and TC2 pins after power-on, always select the power-off mode ($\overline{\text{POFF1}} = \overline{\text{POFF2}} = \text{VI}$) and replace them by each other.

Voltage Regulator Circuit

The voltage regulator circuit regulates a voltage entered in the V_{RI} pin and can output any voltage. It uses the series voltage regulation. As shown in Figure 2.5, the V_{RI} and V_O pins must be short-circuited by a jumper as short as possible except for larger time boosting by using external diodes.

As shown by equation (1), any output voltage can be set by the ratio of external division resistors R₁ and R₂. The sum of division resistance is recommended to be

small as possible to avoid an external noise interference. As the current consumed by division resistors (equation (2)) flows, the 100Ω to 1MΩ are recommended to use.

The temperature coefficient of the regulated voltage is equal to the temperature coefficient of the reference voltage that is explained in the “reference voltage circuit” section.

Figure 2.5 VREG setup and mounting notes

Setup:

- Relationship between VREG and reference voltage

$$V_{REG} = \frac{R1 + R2}{R1} \times (\text{Reference voltage}) \quad \dots \text{Equation (1)}$$

- Current consumption of division resistors

$$I_{REG} = \frac{|V_{REG}|}{R1 + R2} \quad \dots \text{Equation (2)}$$

Setup example:

- To output VREG = -18 V by four-time boosting if Vi = -5 V and Vo = -20 V

First, determine the total resistance of division resistors R1 and R2. If the current consumption is assumed to be 20 μA , the total resistance can be obtained from equation (2) as follows:

$$R1 + R2 = 12\text{V} \div 20\ \mu\text{A} = 900\ \text{k}\Omega$$

If the reference voltage is -1.5 V, the division resistance ratio can be obtained from equation (1) as follows:

$$(R1 + R2) / R2 = (-18\ \text{V}) \div (-1.5\ \text{V}) = 12$$

Therefore, R1 and R2 are:

$$\begin{aligned} R1 &= 75\ \text{k}\Omega \\ R2 &= 825\ \text{k}\Omega \end{aligned}$$

Changing the temperature coefficient:

- The temperature coefficient of the regulated voltage depends on the temperature coefficient of the reference voltage (if the division ratio of setup resistors does not depend on the temperature). It is necessary to change the temperature coefficient using thermistors, resistors or others to set any other temperature coefficient of the regulated voltage. The following explains how to calculate the VREG voltage in temperature T.

$$V_{REG}(T) = \left\{ 1 + \frac{CTR2 \times R2(T_0)}{CTR1 \times R1(T_0)} \right\} \times \left[1 + (T - T_0) \times \frac{CT}{100} \right] \quad \dots \text{Equation (3)}$$

T ₀	: 25°C
CTR1	: Temperature coefficient of resistor R1 (Ratio to the value at 25°C)
CTR2	: Temperature coefficient of resistor R2 (Ratio to the value at 25°C)
CT	: Temperature coefficient of internal reference voltage (%/°C)
R1 (T ₀)	: R1 value (Ω) at 25°C
R2 (T ₀)	: R2 value (Ω) at 25°C
VREF (T ₀)	: Internal reference voltage (V) at 25°C

If the temperature coefficient of R1 and R2 is identical in equation (3), the VREG voltage depends on the temperature coefficient of internal reference voltage only.

Application notes on voltage regulator circuit:

- To satisfy the absolute maximum ratings of the S1F76540, the setup resistor(s) must be inserted between VDD and VREG pins of the S1F76540 that uses the voltage regulator. The S1F76540 IC itself may be degraded or destroyed if the R1 resistor is connected to pin VDD of S1F76540 that does not use the regulator during serial connection.
- The regulation voltage adjustment input (pin RV) has the very high input impedance, and its noise insertion can drop the regulator stability. As shown in Figure 2.5, shield the cable between the division resistor and RV pin or use a cable as short as possible between them.

Power-off Control Function

The S1F76540 has the power-off function and turns on or off each circuit function when control signals are entered in the $\overline{\text{POFF1}}$ and $\overline{\text{POFF2}}$ pins from an external system (such as microprocessor) as defined on Table 2.7. This power-off function can also cut the reactive current

in parallel connection and other application circuits. To use the dual-state, power-off control (all ON and all OFF states) only, connect pin $\overline{\text{POFF2}}$ to pin V_I and use only pin $\overline{\text{POFF1}}$ for power-off control.

Table 2.7 Available combination of power-off control

Mode	$\overline{\text{POFF1}}$ (High = V_{DD}) (Low = V_I)	$\overline{\text{POFF2}}$ (High = V_{DD}) (Low = V_I)	Functions				Applications
			Oscillator	Booster circuit	Regulator circuit		
PS1	High	Low	ON	ON	ON		All circuits are turned on.
PS2	Low	Low	OFF	OFF (*1)	OFF (*2)		All circuits are turned off.
PS3	High	High	OFF	ON	ON		Slave unit side of parallel connection (Booster and regulator)
PS4	Low	High	ON	ON	OFF		Master unit side of parallel connection (Booster only)

*1 When the booster circuit is off, approximately $V_I + 0.6 \text{ V}$ voltage appears at V_O pin.

*2 When the regulator is off, the V_{REG} pin becomes high-impedance state.

Application notes on power-off function:

- When using external system signals for power-on control, start to control the power only when V_I voltage becomes stable after power-on. Unstable V_I voltage may destroy the IC permanently during on/off control.

Figure 2.6 Start timing of power-off control

CHARACTERISTICS GRAPH

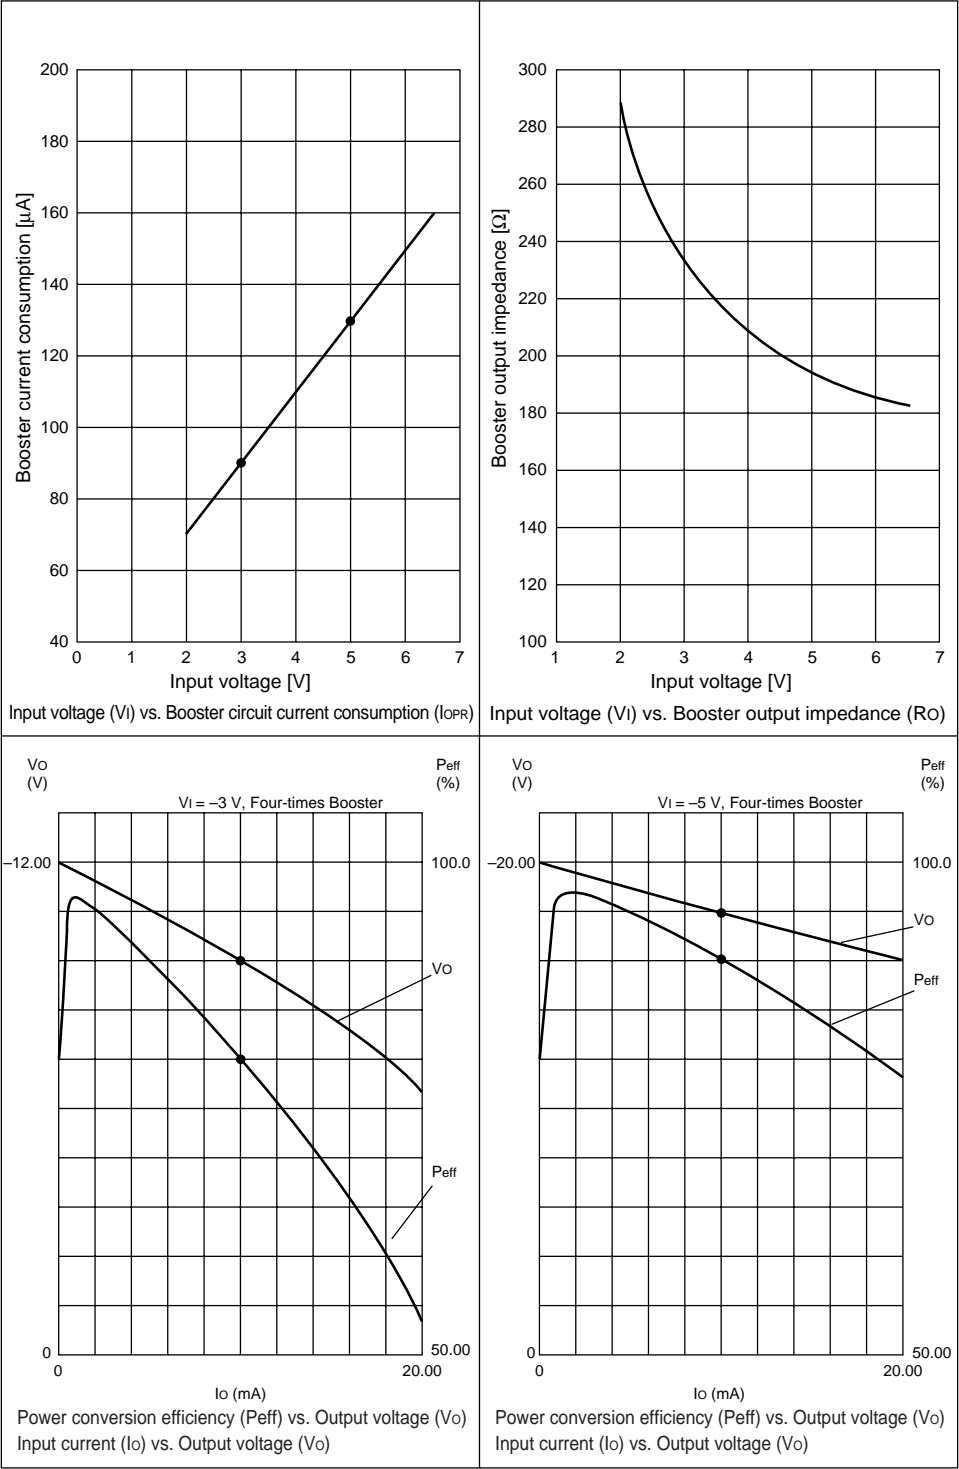

Figure 2.7 Characteristics graphs

APPLICATION CIRCUIT EXAMPLES

Four-time Booster and Regulator

Figure 2.8 gives a wiring example of four-time booster and regulator that is the typical S1F76540 application. This example boosts the input voltage (V_I) four times in

negative direction, and outputs the regulated voltage at V_{REG} pin.

Figure 2.8 Wiring example of 4-time booster and regulator

◇ Setup conditions of Figure 2.8

- Internal clock : ON (Low Output mode)
- Booster circuit : ON
- Regulator : ON (if $C_T = -0.04\%/^{\circ}\text{C}$)

◇ Power-off procedure

- Set the $\overline{\text{POFF1}}$ pin to logical low (V_I) to turn off all circuits.

◇ Regulator

- For the regulator setup and notes, see the “voltage regulator circuit” section.

◇ Application in other setup conditions

- ① When used in the High Output mode
 - Connect the FC pin to the V_I pin.
- ② When changing the temperature coefficient (C_T)
 - Change the TC1 and TC2 pin setup by following the definition of Table 2.7.

4-time Booster

Only the booster circuit operates, and it boosts the input voltage (V_I) four times in negative direction and outputs it at the V_O pin. As the regulator is not used, the voltage

appearing at the V_O pin may contain ripple components. Figure 2.9 gives a wiring example.

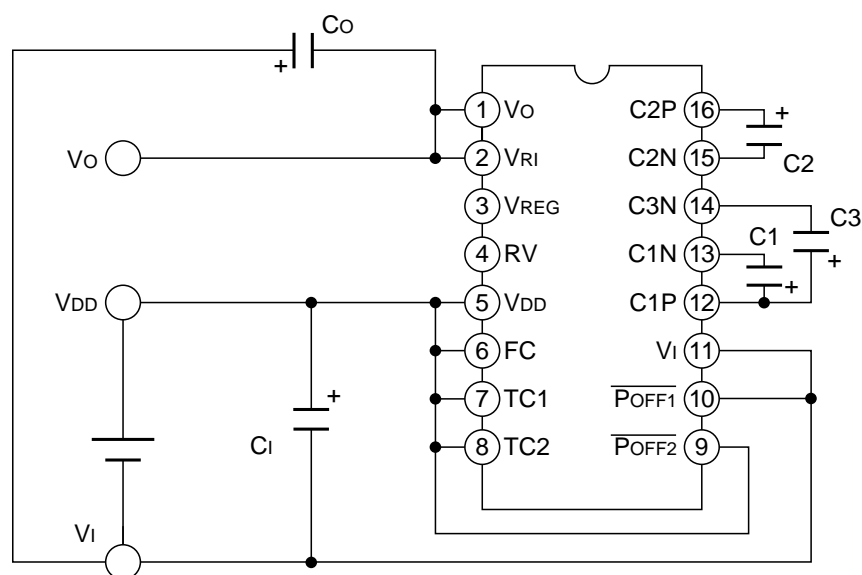

Figure 2.9 Wiring example of 4-time booster

◇ Setup conditions of Figure 2.9

- Internal clock : ON (Low Output mode)
- Booster circuit : ON
- Regulator : OFF

◇ Power-off procedure

- Set the $\overline{\text{POFF2}}$ pin to low (V_I) to turn off all circuits.

◇ Ripple voltage

- As the output at V_O pin is unstable, it can contain ripple components as shown in Figure 2.10. The ripple voltage (V_{RP}) increases according to the load current, and it can roughly be calculated by equation (4).

$$V_{RP} = \frac{I_o}{2 \cdot f_{CL} \cdot C_o} + I_o \cdot R_{COUT} \quad \dots \text{Equation (4)}$$

where,

I_o : Load current (A)

fCL : Clock frequency (Hz)

RCOUT : Serial equivalent resistance (Ω) of output capacitor Co

Figure 2.10 Ripple waveforms

- ◇ Application in other setup conditions
- ① When used in the High Output mode
Connect the FC pin to the VI pin.

Parallel Connection (for Increased Boosting)

The parallel connection is useful for reduction of booster output impedance or reduction of ripple voltage. In the parallel connection of “n” lines, the booster output impedance can be reduced to approximately “1/n”. Only the smoothing capacitor (Co) for booster output can be used commonly in the parallel connection. When using the regulator, use only one of “n”

S1F76540 chips which are in parallel connection. (If multiple regulators are operated in parallel mode, the reactive current consumption occurs.) Figure 2.11 gives a wiring example of 4-time booster and regulator where two S1F76540s are parallelly connected.

Figure 2.11 Parallel connection example

◇ Setup conditions of Figure 2.11

- | First stage | Second stage |
|---|---|
| • Internal clock : ON (Low Output mode) | • Internal clock : OFF |
| • Booster circuit : ON | • Booster circuit : ON |
| • Regulator : OFF | • Regulator : ON (if $C_T = -0.04\%/^{\circ}\text{C}$) |

◇ Power-off procedure

- In Figure 2.11, when the $\overline{\text{POFF2}}$ pin of the first-stage S1F76540 is set to low (V_I), voltage boosting is stopped at the first and second stages. However, the regulator at the second stage does not stop. Therefore, the voltage that is approximately V_I appears at V_{REG} pin during $|V_{\text{REG}}| > |V_I|$ setup.
- To set the V_{REG} pin to high-impedance state, set both $\overline{\text{POFF1}}$ and $\overline{\text{POFF2}}$ pins to low at the first and second stages.

◇ Application in other setup conditions

- ① When used in the High Output mode
 - Connect the FC pin of the first-stage S1F76540 to the V_I pin.
- ② When changing the temperature coefficient (C_T)
 - Change the TC1 and TC2 pin setup by following the definition of Table 2.7.

Larger Time Boosting Using Diodes

The S1F76540 can be configured to have the five-time or larger voltage boosting and regulation by adding external diodes. As the booster output impedance increases due to the diode forward voltage drop (V_F), the diodes having a smaller V_F are recommended to use.

Figure 2.12 gives a wiring example of 6-time booster and regulator that use two diodes. The wiring between V_O and V_I must be minimal. Figure 2.13 provides the potential relationship.

Figure 2.12 Wiring example for 6-time boosting using diodes

◇ Setup conditions of Figure 2.12

- Internal clock : ON (Low Output mode)
- Booster circuit : ON
- Regulator : ON (if $C_T = -0.04\%/^{\circ}\text{C}$)

Figure 2.13 Potential relationship during 6-time boosting using diodes

◇ Power-off procedure

- Set the $\overline{\text{POFF1}}$ pin to low (V_I) to turn off all circuits.

◇ Output voltages

- When diodes are used for voltage boosting, the characteristics of diodes directly affect on the voltage boosting characteristics. The forward voltage drop (V_F) of diodes can reduce the booster output voltage. As the example of Figure 2.12 uses two diodes, the drop of “ V_F ” voltage multiplied by two occurs as shown in Figure 2.13. The booster output voltage is expressed by equation (5).

To increase the $|V_{O'}|$ value, use the diodes having a smaller V_F .

$$|V_{O'}| = 6 \times |V_I| - 2 \times V_F$$

• • • • Equation (5)

◇ Notes

① Input and output current conditions

To satisfy the input and output current ratings, limit the total current does not exceed the rated input current. The total current means the total boost time multiplied by the output load current. The example of Figure 2.12 has the maximum load current of 13.3 mA (= 80 mA divided by 6).

② Input and output voltage conditions

To satisfy the input and output voltage ratings, take care not to violate the electric potential relationship of higher time boosting using diodes. The example of Figure 2.12 must have the “ V_I ” that can satisfy the input voltage conditions during 6-time boosting (see Table 2.3).

◇ Application in other setup conditions

① When used in the High Output mode

Connect the FC pin to the V_I pin.

② When changing the temperature coefficient (C_T)

Change the TC1 and TC2 pin setup by following the definition of Table 2.7.

Positive Voltage Conversion

The S1F76540 can also boost up a voltage to the positive potential using external diodes. In such case, however, the regulator function is unavailable. Figure 2.14

gives a wiring example for three-time positive boosting, and Figure 2.15 provides its electrical potential relationship.

Figure 2.14 Wiring example of positive voltage conversion (3-time boosting)

- ◇ Setup conditions of Figure 2.14
- Internal clock : ON (Low Output mode)
 - Booster circuit : ON
 - Regulator : OFF

Figure 2.15 Potential relationship during positive voltage conversion (3-time boosting)

- ◇ Power-off procedure
- Set the $\overline{\text{POFF2}}$ pin to low (V_I) to turn off all circuits.
- ◇ Two-time boosting
- To boost up a voltage two times, remove capacitor C1 and diode D1 of Figure 2.14, and connect the anode of diode D2 to the VDD pin.

◇ Output voltages

- When diodes are used for voltage boosting, the characteristics of diodes directly affect on the voltage boosting characteristics. The forward voltage drop (V_F) of diodes can reduce the booster output voltage. As the example of Figure 2.14 uses three diodes, the drop of “ V_F ” voltage multiplied by three occurs. The booster output voltage is expressed by equation (5).

To increase the $|V_O|$ value, use the diodes having a smaller V_F .

$$|V_O| = 3 \times |V_I| - (3 \times V_F)$$

•••• Equation (6)

◇ Notes

① Input and output current conditions

To satisfy the input and output current ratings, take care to limit the input current below the ratings.

② Input and output voltage conditions

During forward voltage conversion, the input voltage ratings are the same as two-time negative voltage boosting (see Table 2.3).

◇ Application in other setup conditions

When used in the High Output mode, connect the FC pin to the V_I pin.

Wiring Example When Changing the Regulator Temperature Coefficient

The temperature coefficient of the regulator depends on the temperature coefficient of the internal reference

voltage. To set another temperature coefficient, use a thermistor resistor or others as shown in Figure 2.16.

Figure 2.16 Wiring example when changing the regulator temperature coefficient

◇ Setup conditions of Figure 2.16

- Internal clock : ON (Low Output mode)
- Booster circuit : ON
- Regulator : ON
- Thermistor resistor : RT

◇ Power-off procedure

- Set the $\overline{\text{POFF1}}$ pin to low (V_I) to turn off all circuits.

◇ Regulator temperature coefficient

- For the regulator setup and notes, see the “voltage regulator circuit” section of the function.
- The thermistor resistor (RT) has the non-linear temperature characteristics. To correct them to the linear characteristics, insert the RP as shown Figure 2.16.

◇ Application in other setup conditions

- When used in the High Output mode, connect the FC pin to the V_I pin.

S1F76640 Series CMOS DC/DC Converter & Voltage Regulator

DESCRIPTION

S1F76640 is a high efficiency and low power consumption CMOS DC/DC converter. It is roughly divided into two portions, step-up circuit and stabilization circuit. The step-up circuit can provide 2 times step-up outputs (3.6 to 11V), 3 times step-up outputs (5.4 to 16.5V) or 4 times step-up outputs (7.2 to 22V) of input voltages (1.8 to 5.5V). If external parts (diode, capacitor) are attached to it, it can realize step-up operations of higher magnifications.

The stabilization circuit enables to set outputs to any voltages. Since the stabilization circuit can provide three kinds of minus temperature gradients to stabilized outputs, it is optimum as a power supply for liquid crystal display (LCD).

Also, S1F76640 enable to drive ICs (liquid crystal driver, analog IC, etc.), which requires another power supply in addition to logic main power supply, with a single power supply. Also, its small power consumption makes it suitable as a micro power supply for handy devices like hand-held computer.

FEATURES

- High efficiency and low power consumption CMOS DC/DC converter
- Easy three kinds voltage conversions to positive potential side from input voltage VDD (+3.3V)
· From input voltage VDD (+3.3V) to outputs 2×VDD (+6.6V), 3×VDD (+9.9V) and 4×VDD (+13.2V).
- Attachment of external parts (diode, capacitor) makes step-up operations of higher magnifications possible.
- Built-in output voltage stabilization circuit
· External resistor enables to set any output voltages.
- Output current : Max. 20mA (VDD=+5V)
- Power conversion efficiency : Typ. 95%
- 3 kinds of reference voltages with negative temperature gradient characteristic suitable for LCD drive power supply can be selected.
- Power off operation by external signal
· Static current at power off time : Max. 2μA
- Possibility of high magnification step-up operation by series connection
- Low voltage operation Optimum for battery drive
- Built-in CR oscillator
- SSOP2-16pin S1F76640M0A0
Bare Chip S1F76640D0A0
- Radiation-resistant design has not been provided for this specification.

PIN ASSIGNMENTS

SSOP2-16pin

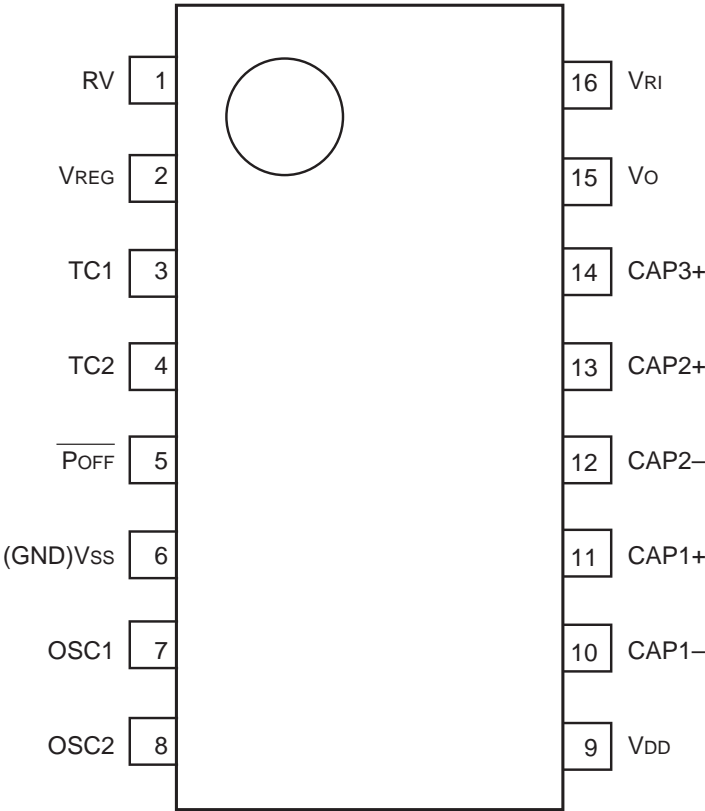

Figure 4-2 Pin Assignments of SSOP2-16pin

PIN DESCRIPTIONS

Pin No.	Pin name	Description
1	RV	Stabilization voltage regulation pin. When the intermediate tap of the external volume (3-pin resistor) connected between the VDD pin and the VREG pin is connected to the RV pin, VREG output voltage can be adjusted.
2	VREG	Stabilized voltage output pin
3	TC1	Temperature gradient selection pin
4	TC2	Temperature gradient selection pin
5	$\overline{\text{POFF}}$	VREG output ON/OFF control pin. When control signal from the system side is input to this pin, the power off (VREG output power off) control of S1F76640 becomes available.
6	GND	Power supply pin (minus side, system GND)
7	OSC1	Oscillation resistor connection pin. This pin becomes the clock input pin when an external clock operates.
8	OSC2	Oscillation resistor connection pin. This pin is released when an external clock operates.
9	VDD	Power supply pin (plus side, system VCC)
10	CAP1-	Pump up capacitor minus side connection pin for 2 times step-up. Next stage clock at series connection time.
11	CAP1+	Pump up capacitor plus side connection pin for 2 times step-up
12	CAP2-	Pump up capacitor minus side connection pin for 3 times step-up. Output pin at 2 time step-up time (to be short-circuited to Vo).
13	CAP2+	Pump up capacitor plus side connection pin for 3 times step-up
14	CAP3+	Pump up capacitor plus side connection pin for 4 times step-up. Output pin at 3 times step-up time (to be short-circuited to Vo).
15	Vo	Output pin at 3 times step-up time
16	VRI	Stabilization circuit input pin

FUNCTIONAL DESCRIPTIONS

CR Oscillator

S1F76640 has a built-in CR oscillator as the internal oscillator, and an external oscillation resistor ROSC is connected between the pins OSC1 and OSC2 before operation. (Figure 5.1)

Figure 5-1 CR Oscillator

Figure 5-2 External Clock Operation

Note 1 : Since the oscillation frequency varies with wiring capacitance, make the cables between the terminals OSC1 and OSC2 and ROSC as short as possible.

When setting the external resistor ROSC, find the oscillation frequency fOSC that brings about the maximum efficiency from Figures 6.5.12 and 6.5.13 and find ROSC suitable for the fOSC from Figure 6.5.1. The relations between ROSC and fOSC in Figure 6.5.1 are expressed approximately with the following formula as far as the straight portion ($500\text{k}\Omega < \text{ROSC} < 2\text{M}\Omega$) is concerned:

$$\text{ROSC} = A \cdot \frac{1}{f_{\text{OSC}}} \left[A : \text{Constant, When GND is 0V and } V_{\text{DD}} \text{ is 5V, } A \text{ is } 2.0 \times 10^{10} (1/\text{F}). \right]$$

So, the ROSC value can be obtained from this formula.

(Recommended oscillation frequency : 10kHz to 30kHz (ROSC : $2\text{M}\Omega$ to $680\text{k}\Omega$))

When the external clock operates, make the pin OSC2 open as shown in Figure 5.2 and input the 50% duty of the external clock from the pin OSC1.

Voltage Conversion Circuits (I) and (II)

The voltage conversion circuits (I) and (II) doubles and triples the input voltage VDD respectively by using clock generated in the CR oscillator.

In case of 2 times step-up, 2 times step-up output of the input voltage is obtained from the VO pin when a pump up capacitor is connected between CAP1+ and CAP1-, CAP2+ and CAP3+ are short-circuited to VO and a smoothing capacitor is connected between VDD and VO outside.

In case of 3 times step-up, 3 VDD is output from the VO pin when a pump up capacitor is connected between CAP1+ and CAP1- and between CAP2+ and CAP2- respectively and a smoothing capacitor is connected between the VDD and VO pins outside.

In case of 4 times step-up, 4 VDD is output from the VO pin when a pump up capacitor is connected between CAP1+ and CAP1-, between CAP2+ and CAP2- and between CAP1+ and CAP3- respectively and a smoothing capacitor is connected between the VDD and VO pins outside.

When GND is 0 and VDD is 5, the relations between the input voltage and the output voltage are as shown in Figures 5-3, 5-4 and 5-5.

Figure 5-3
Example of 2 times step-up
potential relations

Figure 5-4
Example of 3 times step-up
potential relations

Figure 5-5
Example of 4 times step-up
potential relations

- Note 1 : At the 3 times step-up time, 2 times step-up output (–10V) cannot be taken out from the CAP2– pin.
 Note 2 : At the 4 times step-up time, 2 times step-up output (–10V) cannot be taken out from the CAP2– pin.
 Note 3 : At the 4 times step-up time, 3 times step-up output (–15V) cannot be taken out from the CAP3– pin.

Reference Voltage Generator, Voltage Stabilization Circuit

The reference voltage generator generates reference voltage necessary for operation of the voltage stabilization circuit and adds temperature gradient to reference voltage. Three temperature gradients are available, and signal from the temperature gradient selection circuit select one of them.

The voltage stabilization circuit stabilizes the step-up output voltage V_O and outputs optional voltages. When an external resistor R_{RV} is connected as shown in Figure 5-5 and the potential of the intermediate tap is changed, V_{REG} output voltage can be set to optional voltages between the reference voltage V_{RV} and V_O .

Figure 5-6 Voltage Stabilization Circuit

The voltage stabilization circuit has power off function and can control ON/OFF of V_{REG} output according to signals from the system side (microprocessor, etc.) When \overline{POFF} is high (V_{DD}), V_{REG} output is turned on, and when \overline{POFF} is Low (GND), it is turned off. When the control is not necessary, \overline{POFF} is fixed to High (V_{DD}).

Temperature Gradient Selection Circuit

S1F76640 can provide three kinds of temperature gradients suitable for driving LCD to VREG output as shown Table 5-1.

Table 5-1 Temperature Gradient Adaptation Table

$\overline{\text{POFF}}$ (Note 1)	TC2 (Note 1)	TC1 (Note 1)	Temperature Gradient C_T (Note 2)	VREG Output	CR Oscillator	Remarks —
1(VDD)	Low(Vss)	Low(Vss)	−0.40%/ °C	ON	ON	—
1(VDD)	Low(Vss)	High(Vo)	−0.25%/ °C	ON	ON	—
1(VDD)	High(Vo)	Low(Vss)	−0.55%/ °C	ON	ON	—
1(VDD)	High(Vo)	High(Vo)	−0.55%/ °C	ON	OFF	Series connection (Note 4)
0(Vss)	Low(Vss)	Low(Vss)	—	OFF(Hi-Z)(Note 3)	OFF	—
0(Vss)	Low(Vss)	High(Vo)	—	OFF(Hi-Z)(Note 3)	OFF	—
0(Vss)	High(Vo)	Low(Vss)	—	OFF(Hi-Z)(Note 3)	OFF	—
0(Vss)	High(Vo)	High(Vo)	—	OFF(Hi-Z)	ON	Boosting only (Note 5)

Note 1 : Please note that potentials on the High side are different between the $\overline{\text{POFF}}$ pin and TC2/TC1 pin.

Note 2 : The formula below is used to define temperature gradient C_T :

$$C_T = \frac{V_{\text{REG}}(50^\circ\text{C}) - V_{\text{REG}}(0^\circ\text{C})}{50^\circ\text{C} - 0^\circ\text{C}} \times \frac{1}{V_{\text{REG}}(25^\circ\text{C})} \times 100 (\%/^\circ\text{C})$$

Example : When $C_T = -0.6\%/^\circ\text{C}$ is selected,

· When T_a is 25°C , the VREG output becomes -8V at 25°C .

$$\Delta V_{\text{REG}}/\Delta T = C_T \cdot |V_{\text{REG}}(25^\circ\text{C})| = -0.6 \times 10^{-2} \times 8 = -48\text{mV}/^\circ\text{C}$$

When the temperature rises 1°C , the $|V_{\text{REG}}|$ value reduces by 48mV .

· When VREG is -10V at 25°C , the formula below is formed:

$$\Delta |V_{\text{REG}}|/\Delta T = -60\text{mV}/^\circ\text{C}$$

Note 3 : At power off time (VREG output : OFF, CR oscillator : OFF), the potential of the Vo output is about $V_{\text{DD}} + 0.5\text{V}$.

Note 4 : When this mode is selected at a series connection, the first stage clock can drive the next stage IC and this mode is effective for reducing the power consumption of the next stage IC. (See Figure 8.4)

Note 5 : Select this mode for boosting only. And the current consumption can be reduced.

ELECTRICAL CHARACTERISTICS

Absolute Maximum Ratings

Parameter	Symbol	Rating		Unit	Remarks
		Min.	Max.		
Input supply voltage	V _{DD}	GND-0.3	24/N	V	V _{DD} N = 2 : 2 times step-up N = 3 : 3 times step-up N = 4 : 4 times step-up

Storage temperature	T _{stg}	-55	150	°C	—
Soldering temperature and time	T _{sol}	—	260 · 10	°C · s	At leads

Note 1 : Under the conditions exceeding the above absolute maximum ratings, the IC may result in a permanent destruction. An operation for a long period under the conditions of the above absolute maximum ratings may deteriorate the reliability remarkably.

Note 2 : All voltage values are based on GND.

Note 3 : The output pins (V_O and V_{REG}) are for stabilizing and outputting boosted voltages. So, they are not used to apply voltage from outside. When voltage is applied from outside for unavoidable reasons, limit the voltage to the rated voltage mentioned above or less.

Note 1 : All voltage values are based on GND being 0V.

Note 2 : The value shown here is the step-up circuit conversion efficiency, and $(V_O - V_{REG})I_{OUT}$ is lost when the stabilization circuit operates. So, it is recommended to operate this so that $(V_O - V_{REG})$ becomes as small as possible. When $(V_O - V_{REG}) \times I_O$ is large, the IC temperature rises and the characteristics of the stabilization circuit change.

Note 3 : See Figures 6-5-14, 6-5-15 and 6-5-16.

Note 4 : RSAT means inclination in Fig. 6-5-17, and $V_O - \Delta$ ($V_O - V_{REG}$) indicates the lower limit voltage of the V_{REG} output.

Note 5 : The calculation formula of C_T is as follows:

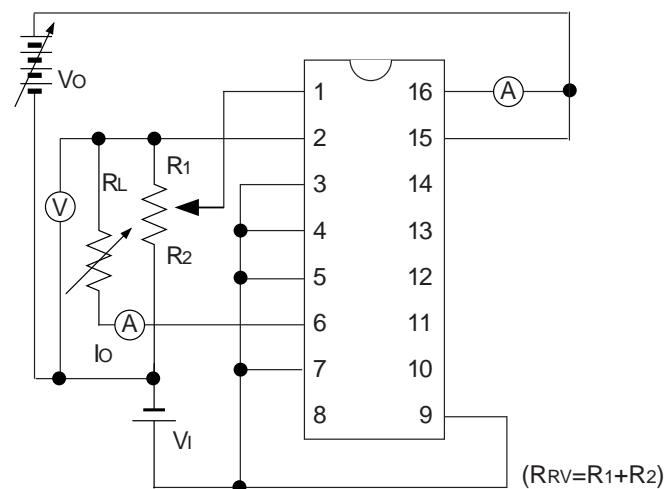

$$C_T = \frac{V_{REG}(50^\circ\text{C}) - V_{REG}(0^\circ\text{C})}{50^\circ\text{C} - 0^\circ\text{C}} \times \frac{1}{V_{REG}(25^\circ\text{C})} \times 100 (\%/^\circ\text{C})$$

APPLICATION EXAMPLE

2 Times Step-up, 3 Times Step-up and 4 Times Step-up

Figure 8.1 shows the connection for getting 4 times step-up output of an input voltage by operating the step-up circuit only. In case of 3 times step-up, the capacitor C3 is removed and CAP3+ (Pin No. 14) is short-circuited to V_O (Pin No. 15), and 3 times step-up voltage is obtained from V_O(CAP3+). In case of 2 times step-up, the capacitor C2 is also removed and CAP2+ (Pin No. 13) is short-circuited to V_O (Pin No. 15), and 2 times step-up voltage (10V) is obtained from V_O (CAP2+).

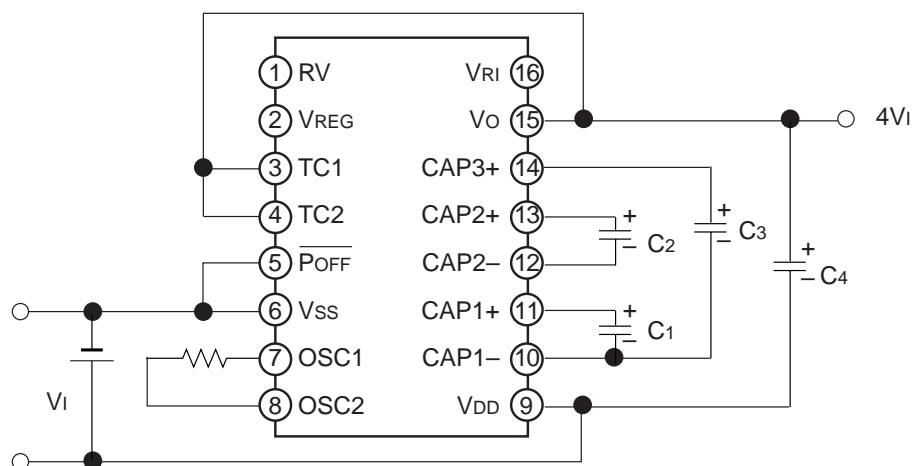

Figure 8-1 4 times step-up circuit

4 Times Step-up + Stabilization Circuit

Figure 8-2 shows an application example for stabilizing step-up outputs obtained in 8-(1) through the stabilization circuit and for providing temperature gradient to V_{REG} output by means of the temperature gradient selection circuit. In this application example, both outputs from V_O and V_{REG} can be indicated at the same time. Also, operation of 3 times step-up + stabilization circuit is possible by using the 3 times step-up operation mentioned in 8-(1), and operation of 2 times step-up + stabilization circuit is possible by using the 2 times step-up operation.

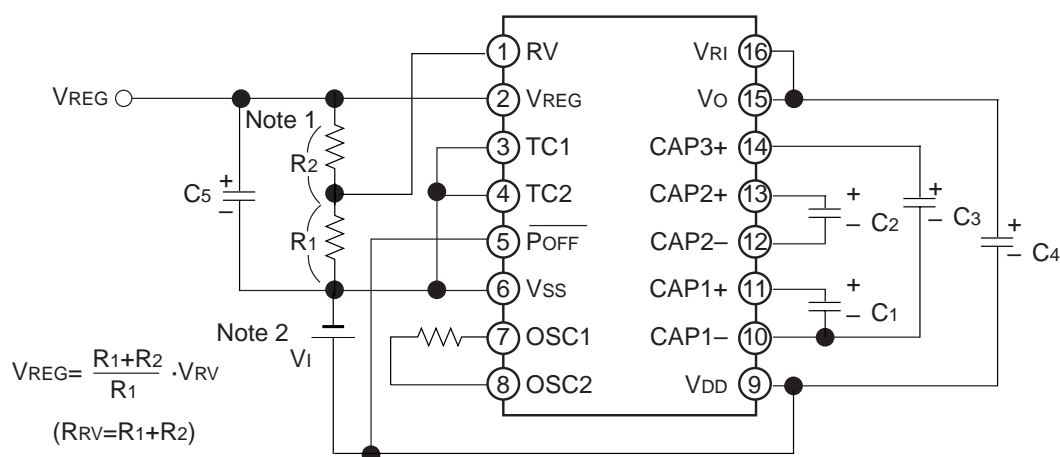

Figure 8-2 Operation of 4 Times Step-up + Stabilization Circuit (Temperature Gradient CT1 is selected.)

Note 1 : Since input impedance at the RV pin (No. 1) is high, it is necessary to use a shielded wire as a measure against noise in case of a long connection. It is also effective to make the RRV value small for reducing noise influence. (In this case, however, more current comes to be consumed at RRV.)

Parallel Connection

It is possible to make the output impedance R_O small when several pieces of the circuit shown in Figure 8.1 are connected. Parallel connection of n circuits reduces R_O to $1/n$ approximately. One piece of the smoothing capacitor C_4 can be commonly used in the same way. To get stabilized outputs after parallel connection, include 1 pieces of the circuit shown in Figure 8.2 in the parallel connection of n circuits as shown in Figure 8.3.

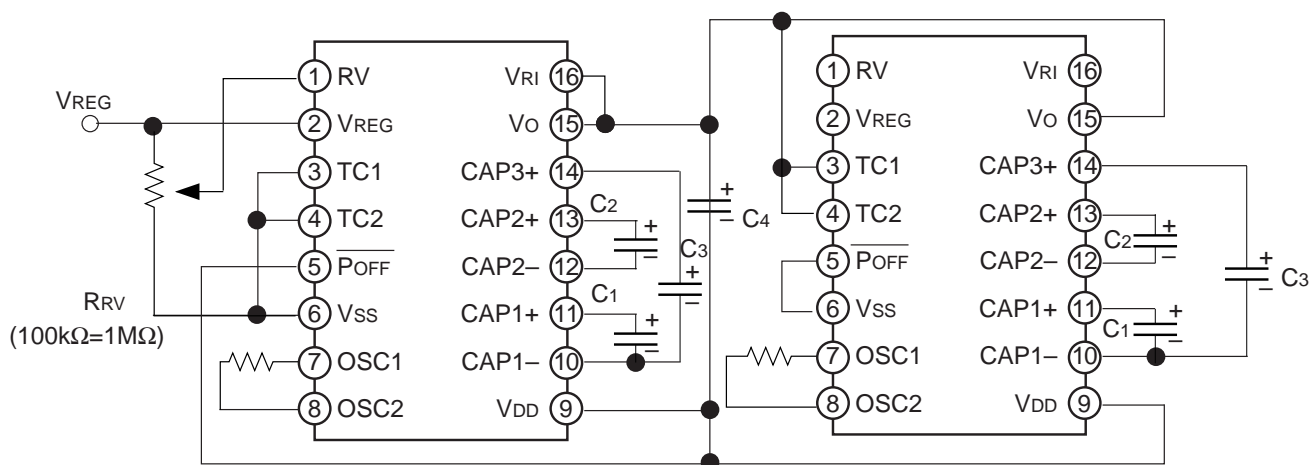

Figure 8.3 Parallel Connection

Series Connection

When S1F76640 is connected in series (V_{DD} and V_O in the previous stage are connected to GND and V_{DD} in the next stage respectively), the output voltage can be increased more. But the series connection makes the output impedance high. Figure 8.4 shows an example of the series connection to get $V_O=25V$ from $V_{DD}=5V$ and to stabilize it.

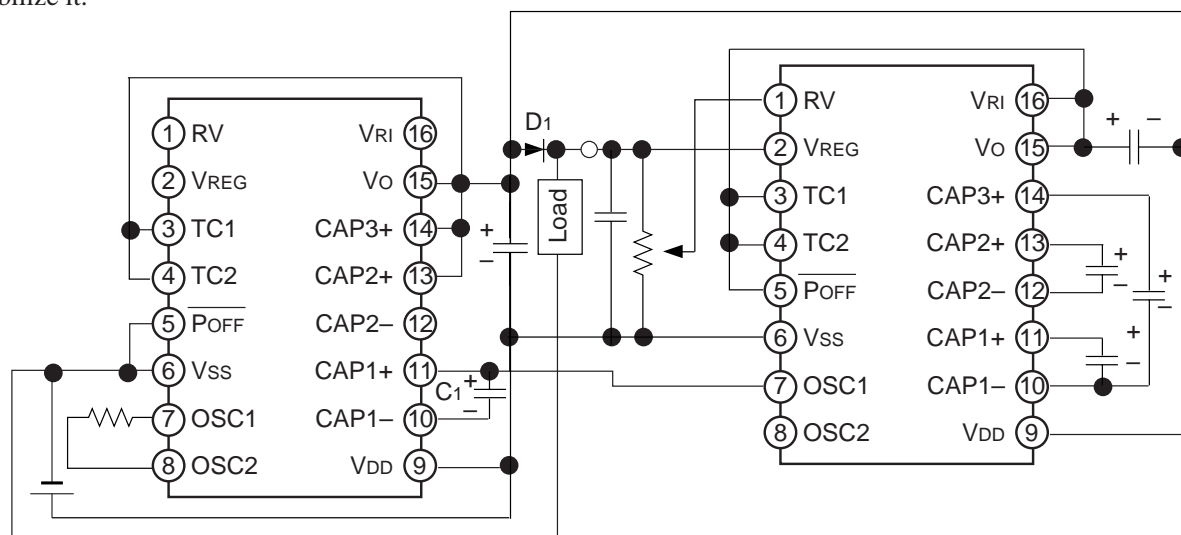

Figure 8.4 Series Connection

Note 1 : Precautions on Load Connection

When a load is connected between GND in the first stage (or potential below GND in the second stage other than that) and VREG in the second stage as shown in Figure 8.4, pay attention to the following. When a normal output is not available at the VREG pin at the starting time or when the $\overline{\text{POFF}}$ signal turns off VREG, current may flows from GND in the first stage (or potential below GND in the second stage other than that) to the VREG pin in the second stage through the load and a voltage higher than the absolute maximum rating below GND in the second stage may be generated at the VREG pin. As a result, the IC may not work normally. For series connection, connect the diode D1 between VDD and VREG in the second stage as shown in Figure 8.4, so that no potential below GND in the second stage is added to the VREG pin.

Note 2 : Figure 8.4 shows 3 times step-up in the first stage and 4 times step-up in the next stage, but 4 times step-up is possible both in the first stage and in the next stage unless the input voltage $\text{VDD}'\text{-GND}'$ exceeds the specification value (6.0V). This means that each IC in this series connection is requested to satisfy the specification values ($\text{VDD-GND} \leq 6, 0\text{V}$, $\text{Vo-GND} \leq 24\text{V}$). (See Figure 8.5.)

Figure 8.5 Power Supply System in Series Connection

Note 3 : 2 times step-up in the first stage allows using the CAP- output in the first stage as the next stage clock, but 3 times step-up does not. Attach an external ROSC as the next stage clock for internal oscillation. Also, since the next stage external clock can operate according the CAP- output in the previous stage as shown in Table 4.1 only when the temperature gradient C_T is $-0.6\%/^{\circ}\text{C}$, use the internal oscillator in the same way when other temperature gradients are necessary.

Note 4 : In case of series connection, the voltage VDD-VREG ($\text{VREG}'\text{-VDD}'$ in Figure 8.5) of the IC, for which the stabilization circuit operates, has temperature gradient. This means that VREG changes at the following rate as temperature changes:

$$\frac{\Delta |\text{VREG}|}{\Delta T} = C_T (\text{VREG}' (25^{\circ}\text{C}) - \text{GND}')$$

Negative Voltage Conversion

S1F76640 can boost input voltage to negative power on the negative potential side by using the circuit shown in Figure 8.6. (In case of 3 times step-up, remove the capacitor C3 and the diode D4 and short-circuit the both ends of D4. In case of 2 times step-up, remove the capacitor C2 and the diode D3 and short-circuit the both ends of D3.) But the output voltage drops by the forward voltage V_F of the diode. When GND is 0V, V_{DD} is 5V and V_F is 0.6V as shown in Figure 8.6 for example, V_O is calculated as follows: $V_O = -15V - 4 \times 0.6V = -12.6V$ (In case of 3 times step-up, V_O is calculated to $-10V - 3 \times 0.6V = -8.2V$, and in case of 2 times step-up, V_O is calculated to $-5V - 2 \times 0.6V = -3.8V$.)

Figure 8.6 Negative Voltage Conversion (Example of 3 times step-up circuit)

Negative Voltage Conversion + Positive Voltage Conversion

When the 3 times step-up operation shown in Figure 8.1 and the positive voltage conversion in Figure 8.6 are combined, the circuit shown in Figure 8.7 can be formed and 20V and $-12.6V$ can be obtained from the input 5V. However, the output impedance is higher than in case of connection of either one only (the negative voltage conversion or the positive voltage conversion).

Figure 8.7 Negative Voltage Conversion + Positive Voltage Conversion

Example of Temperature Gradient Change by External Temperature Sensor (Thermistor)

S1F76640 has a temperature gradient selection circuit inside the stabilization circuit, and three kinds of temperature gradients, $-0.20\%/^{\circ}\text{C}$, $-0.40\%/^{\circ}\text{C}$ and $-0.60\%/^{\circ}\text{C}$, can be selected as the VREG output. When other temperature gradients are necessary, a thermistor is connected in series to the resistor RRV for output voltage regulation as shown in Figure 8.8, and temperature gradients can be changed to any values.

Figure 8.8 Example of Temperature Gradient Change

(Pins other than the above Pins 1, 2 and 6 are connected as per Figure 5.2. For Pins 3 and 4, smaller temperature gradients than those to be changed are selected from Table 4.1 and are set.)

Note 1 : Relations among the thermistor, R_T and VREG are expressed as follows:

$$V_{REG} = \frac{R_{RV} + R_T}{R_1} \cdot V_{RV}$$

When a thermistor is used for R_T , it can make the temperature gradient of VREG larger..

Note 2 : The thermistor temperature characteristics are non-linear but can be corrected to linear ones when the resistor R_P is connected to the thermistor in parallel.

Configuration Example of Voltage Stabilized Output (VREG) Electronic Volume Circuit

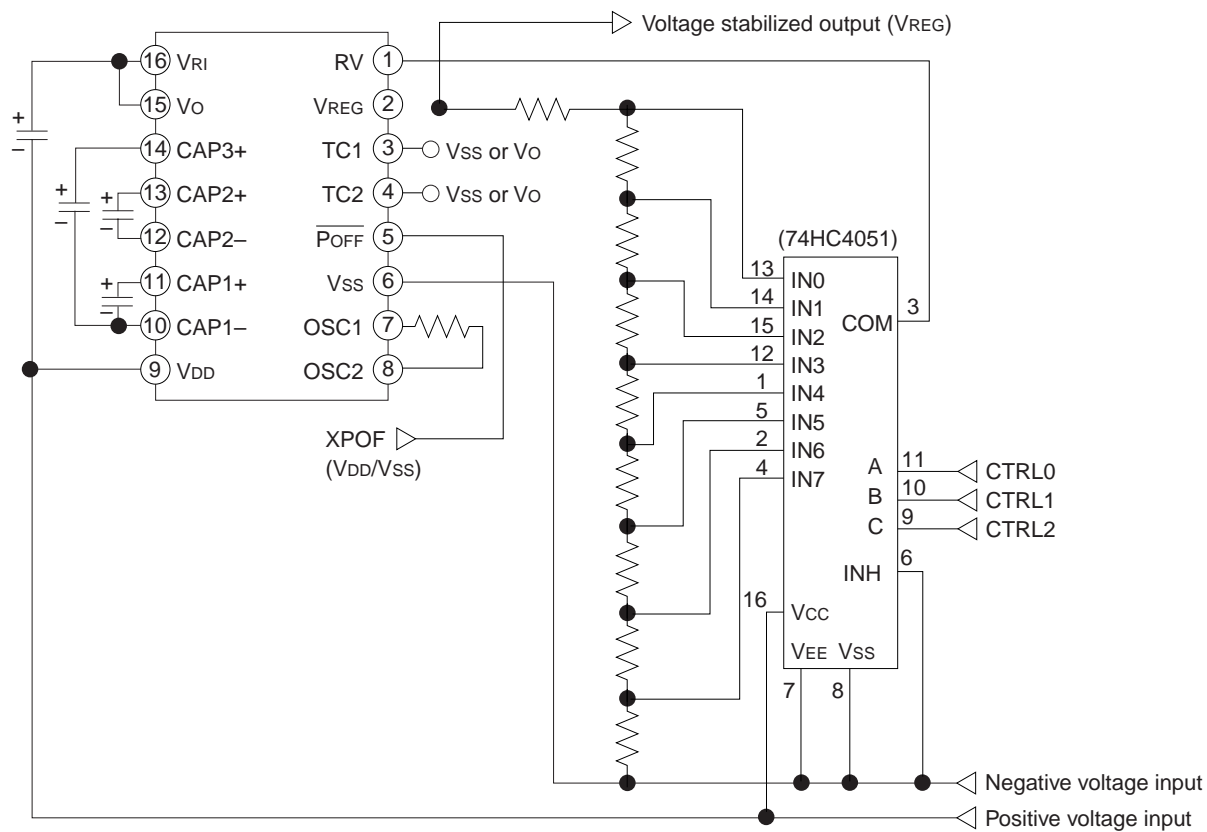

Figure 8.9

Configuration Example of High Magnification Step-up Circuit with Diode

S1F76640, if an external diode is attached, can realize 5 times or more step-up operation and voltage stabilized output. Since the forward voltage drop V_F of the diode makes the output impedance of the step-up output higher, it is recommended to use a diode of small V_F . Figure 8.10 shows a configuration example of a circuit with 2 diodes, which realizes 6 times step-up operation and voltage stabilized output. Make the wire between VO and VRI as short as possible. Figure 8.11 shows the potential relations diagram

By the way, use the voltage applied to the VRI pin below the absolute maximum rated voltage.

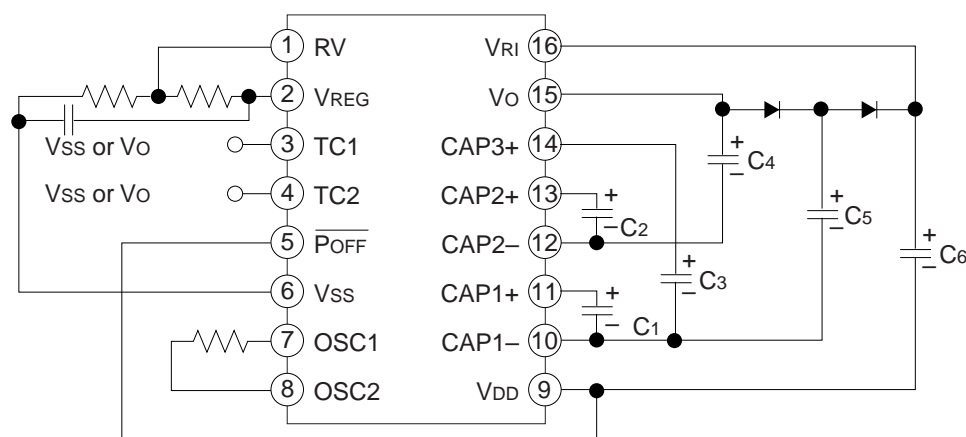

Figure 8.10 Configuration Example of 6 times step-up Circuit with Diode

Figure 8.11 Potential Relations Diagram of 6 times Step-up Circuit with Diode

3. Voltage Regulator

S1F78100Y Series CMOS Positive Voltage Regulators

DESCRIPTION

SCI78100Y Series is a fixed type positive voltage regulator developed by using the CMOS silicon gate process and is composed of a low current consumption reference voltage circuit, a differential amplifier, an output control transistor and a voltage setting resistor.

The output voltage is fixed inside the IC, and various standard voltage parts are available.

The package is a SOT89-3pin plastic package.

FEATURES

- Ample lineup : 12 kinds are available in the range from 2V to 6V.
- Low current consumption : Typ. $3.0\mu\text{A}$ ($V_{\text{DD}}=5.0\text{V}$)
- Small difference between input and output voltages : Typ. 0.25V ($I_{\text{O}}=-10\text{mA}$, $V_{\text{O}}=5.0\text{V}$)
- Built-in highly stable reference voltage source : Typ. 1.0V
- Small output voltage temperature coefficient : Typ. $+100\text{ppm}/^{\circ}\text{C}$
- Wide operating voltage range : 15V Max.

FUNCTIONAL DESCRIPTIONS

S1F78100Y Series is a fixed positive output type voltage regulator of series regulator system and is fitted with an output control MOS transistor between the input and output pins as shown in the figure below. The voltage regulator feeds back voltages (V_{REG}) divided with the built-in resistors R_1 and R_2 connected between

the output pin (V_O pin) and the V_{SS} pin to compare them with the reference voltage (V_{REF}) and outputs the stable output voltage (V_O) not depending on input voltage by controlling the gate voltage of the output control transistor. The output voltage is fixed inside and is decided with the following formula:

$$V_O = \frac{R_1 + R_2}{R_1} \cdot V_{REF}$$

S1F79100Y Series CMOS Negative Voltage Regulators

DESCRIPTION

S1F79100Y series voltage regulators provide step-down and stabilization for an input voltage to a specified fixed voltage. The four devices in the series incorporate a precision, power-saving reference voltage generator, a transistorized differential amplifier and resistors for determining the output voltage.

The S1F79100Y series is available in 3-pin plastic SOT89s.

FEATURES

- Ample lineup : 5 kinds are available in the range from -1.5V to -5V .
- Small difference between input and output voltage : Typ. 0.17V ($I_o=10\text{mA}$, $V_o=-5.0\text{V}$)

- Built-in highly stable reference voltage source : Typ. -1.0V
- Small output voltage temperature coefficient : Typ. $-100\text{ppm}/^\circ\text{C}$
- Wide operating voltage range : 15V Max.

APPLICATIONS

- Fixed-voltage power supplies for battery-operated equipment such as portable video cassette recorders, video cameras and radios
- Fixed-voltage power supplies for communications equipment
- High-stability reference voltage generators

PACKAGE MARKINGS

The markings on S1F79100Y series device packages use the following abbreviations.

Parameter	Code	Description
Output voltage code	B	5 V
	D	3 V
Voltage regulator code	P	Positive
	N	Negative

Note

The reflow furnace temperature profile requirements must be satisfied during package reflow. Avoid soldering on surface mount package (including SOT89) as it causes a quick temperature change of package and a device damage.

Marking locations

FUNCTIONAL DESCRIPTIONS

Basic Operation

The S1F79100Y series uses a 3-pin series regulator feedback loop. An operational amplifier compares V_{REF} from the voltage divider formed by R₁ and R₂, with V_{REF}. The amplifier output adjusts the output transistor gate bias to equalize the voltages and compensate for fluctuations in V_I.

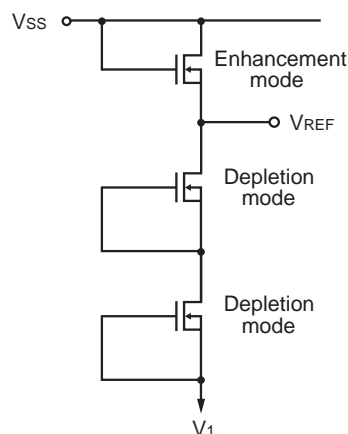

The following equation shows the relationship between V_O and V_{REF}.

$$V_O = \frac{R_1 + R_2}{R_1} V_{REF}$$

Internal Circuits

Reference voltage generator

The offset structure used in all three transistors results in a high breakdown voltage that ensures a stable reference voltage output over a wide range of input voltages.

Differential amplifier

The built-in differential amplifier generates a potential at point X that adjusts the gate bias of the output transistor if there is any difference between VREF and VREG.

Output transistor

The output side of the p-channel MOS transistors in the output transistor circuit is connected to the voltage divider resistors in the feedback loop.

TYPICAL APPLICATIONS

Current Booster

At the cost of a small increase in current consumption, the voltage is regulated while maintaining high current output.

External Voltage Converter

The following circuit raises the output voltage of a S1F79100Y series IC.

The following equation shows the relationship between the old and new voltages.

$$V_O = \frac{R_1 + R_2}{R_2} V_R$$

Note that the application must supply a bias current, I_B , high enough to offset the increase in voltage across R_1 due to I_{OPR} .

An alternative circuit for raising the output voltage is shown in the following figure.

This configuration, however, introduces two design problems.

1. It reduces the output voltage by V_F , the forward voltage drop across the diode.
2. It is sensitive to fluctuations in V_F due to differences in diodes, operating temperatures and I_{SS} .

R_1 helps reduce the affect of I_{SS} on V_F . It is also required when I_{SS} is lower than the diode bias current. For certain input voltages, a Zener diode with the reverse polarity can be used.

High Input Voltages

A preliminary regulator circuit is required to bring the input voltage within the S1F79100Y series rated range.

Switching Output

S1F79100Y series devices are designed for continuous operation. An external switching circuit allows the regulated output to be switched ON and OFF.

Note) Temperatures during reflow soldering must remain within the limits set out under LSI Device Precautions in this catalog. Do not immerse QFP and SOT89 packages during soldering, as the rapid temperature gradient during dipping can cause damage.

4. DC/DC Switching Regulators

The S1F76300 series of CMOS switching regulators comprises nine series—the S1F76310, S1F76380 series

featuring built-in RC oscillators, the S1F76330 series requiring external crystal oscillators.

S1F76310, S1F76380 Series Built-in CR Oscillator Type CMOS Switching Regulators

DESCRIPTION

The S1F76310, S1F76380 series of CMOS switching regulators provide input voltage step-up and regulation to a specified fixed voltage using an external coil. The devices in these series incorporate precision, low-power reference voltage generators and transistors for driving an internal comparator. They feature low power consumption, low operating voltages, voltage detection and standby operation.

The devices offer a range of fixed output voltages, from 2.0 to 5.0V. The S1F76310 series features battery backup and power-on clear, the S1F76380 series features power-on clear and response compensation, the S1F76380 series offer an output voltage temperature characteristic for driving an LCD. They are available in SOP3-8pin.

FEATURES

- 0.9V (Min.) operating voltage
- 10 μ A (Typ.) maximum current consumption
- Standby operation
- 3 μ A (Typ.) standby current consumption
- 1.05 \pm 0.05V high-accuracy voltage detection
- Battery backup (available on S1F76310 series)
- On-chip CR oscillator
- Power-on clear (available on S1F76310 and S1F76380 series)
- Output voltage temperature characteristic for driving an LCD (available on S1F76380 series)
- SOP3-8pin

APPLICATIONS

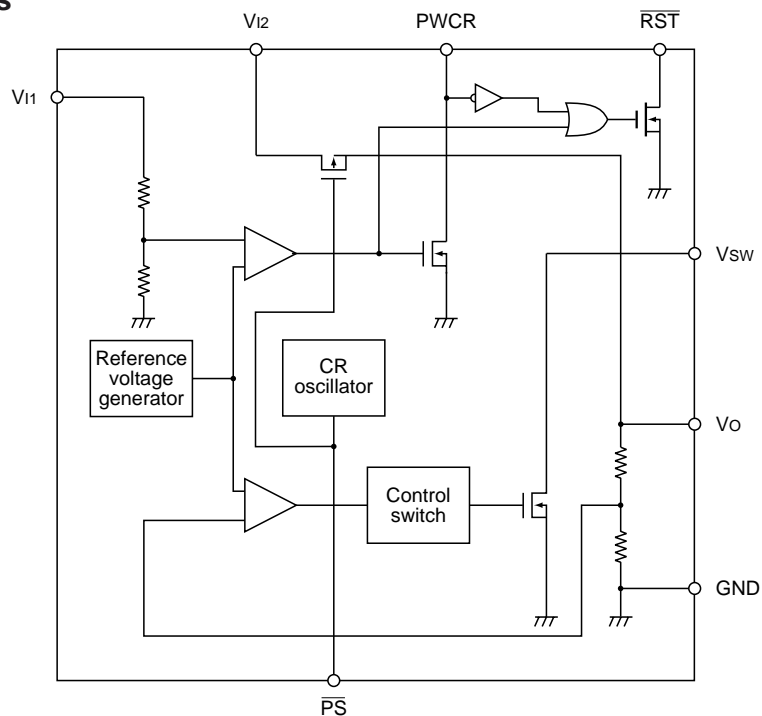

- Fixed-voltage power supplies for battery-operated equipment such as portable video cassette recorders, video cameras and radios
- Power supplies for pagers, memory cards, calculators and similar hand-held equipment
- Fixed-voltage power supplies for medical equipment
- Fixed-voltage power supplies for communications equipment
- Power supplies for microcomputers
- Uninterruptable power supplies
- Power supplies for LCD panel

Measurement circuit

PACKAGE MARKINGS

S1F76310, S1F76380 series device packages use the following markings.

FUNCTIONAL DESCRIPTIONS

Basic Voltage Booster Operation

Tr1 switches ON and OFF at half the frequency of the clock pulses from the built-in RC oscillator. When the transistor is ON, the circuit stores energy in L. When it is off, this energy flows through D to charge C.

Internal Circuits

CR oscillator

The S1F76310, S1F76380 series use a built-in CR oscillator to drive the voltage booster circuit. The circuit is supplied by V11. All circuit components are on-chip and thus the drive frequency is set internally. To ensure 50% duty, this frequency is twice that used by the voltage booster circuit.

When PS is Low, the oscillator is disabled and the chip is in standby mode.

Reference voltage generator and output voltage regulator

The reference voltage generator regulates V_{I1} to generate a voltage for the voltage regulator and voltage detection circuits.

The voltage regulator regulates the boosted output voltage. This is determined by the level at point A between the two resistors connecting V_O and GND. These series use an on-chip resistor to set the output at a specified voltage.

Note

In step-up voltage operation, the ripple voltage created by the switching operation is large relative to the output voltage described above. This ripple voltage is affected by external components and load conditions. The user is advised to check this voltage carefully.

Voltage detection

The S1F76310, S1F76380 series are equipped with a built-in voltage detection function. The detection voltage, V_{DET} , is fixed internally at $1.05 \pm 0.05V$.

Power-on clear function

The S1F76310 series and S1F76380 series are equipped with a built-in power-on clear function. As shown in the following figure, R1 and C1 are connected to PWCR, and R2 is connected to \overline{RST} to operate the function. If V_{I1} drops below V_{DET} , Tr1 and Tr2 conduct and PWCR and \overline{RST} are grounded. If V_{I1} recovers and rises higher than V_{REL} , Tr1 turns OFF. The detection voltage hysteresis is 5% (Typ.) and V_{REL} is $V_{DET} \times 1.05$ (Typ.).

V_O returns to its normal value when the voltage of PWCR increases and Tr2 turns OFF, so that \overline{RST} returns to V_O after a delay specified by the time coefficient of R1 and C1. Thus, after normal output has been obtained, a reset pulse of adjustable width can be obtained which can reset a system connected to \overline{RST} . The output from \overline{RST} is an N-channel, open-drain. When V_{I1} exceeds V_{DET} , the drain is opened and, when V_{I1} drops below V_{DET} again, the output transistor conducts and the output is grounded. The characteristic response is shown in the following figure.

Disabling power-on clear

Always connect PWCR to either V_O or GND. If voltage detection only is required, remove the resistor between PWCR and V_O and monitor the level at \overline{RST} . If neither function is required, connect PWCR to GND. Leaving PWCR unconnected results in an undefined inverter gate voltage in the V_O circuit, causing transient currents to flow between V_O and GND.

Output voltage response compensation

The S1F76380 series are provided with a response compensation input. A response compensation capacitor is connected between VCONT and VO, allowing the ripple voltage generated by the boosted output voltage to be suppressed to a minimum.

Standby mode and battery backup

The S1F76310 series are equipped with a standby mode, initiated by connecting \overline{PS} to GND.

In standby mode, the booster, including the crystal oscillator, is disabled (the switching transistor used to drive the inductor is turned OFF) and the built-in backup switch is turned ON, so that the input voltage at V12 is output at VO. This enables the battery backup function. \overline{PS} is pulled-up internally, so when standby mode is not required, the pin should be left open.

Powering up

Ensure that VO is at least the minimum operating voltage (0.9V) before switching on the booster circuit. One way to do this is to attach a battery so that VO never drops below the minimum required for backup mode. If no such external power supply is available, connect V12 to V11 and hold \overline{PS} Low when applying power for the first time.

TYPICAL APPLICATIONS

Example Circuits

The output current, I_O , and power conversion efficiency, Peff of a particular device in a series depends on

factors such as the switching frequency, type of coil, and the size and type of other external components.

- $\text{Peff} = 80\%$ when $L = 300\mu\text{H}$ (toroidal coil),
 $V_{\text{II}} = 1.5\text{V}$, $f_{\text{CLK}} = 32\text{kHz}$, $I_{\text{O}} = 10\text{mA}$

External components

The performance characteristics of switching regulators depend greatly on the choice of external components. Observing the following guidelines will ensure high performance and maximum efficiency.

Inductor

Use an inductor with low direct-current resistance and low losses.

Leadless

Pre-wound, leadless inductors using surface-mount technology are the most suitable for portable equipment and other space-critical applications.

Drum coil

Avoid using drum coils because their magnetic field can induce noise.

Toroidal coil

Use a toroidal coil to virtually eliminate magnetic field leakage, reduce losses and improve performance.

Diode

Use a Schottky barrier diode with a high switching speed and low forward voltage drop, V_{F} .

Capacitor

To minimize ripple voltages, use a capacitor with a small equivalent direct-current resistance for smoothing.

Other Applications Voltage booster

Combining an S1F76310 switching regulator with an S1F76610C/M DC/DC converter and voltage regulator

creates the voltage booster circuit shown in the following figure.

Potential levels are shown in the following figure.

S1F76310M1A0. The input voltage still reaches the S1F76610C/M through L and D .

Although the circuit appears to have two ON/OFF control points, \overline{PS} on the S1F76310M1A0 and $\overline{P_{OFF}}$ on the S1F76610C/M, \overline{PS} only shuts down the

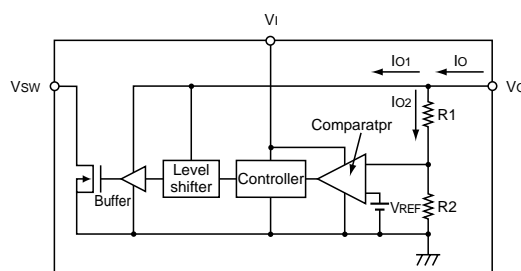

Output voltage adjustment

To ensure stable output, any circuit that adjusts the output voltage must contain C1, RA and RB. To stop switching current from affecting VO, the circuit must also satisfy the condition $I_O < I_R$.

The following figure summarizes the relevant circuits inside an S1F76300 series chip.

V_O is connected to the level shift and buffer circuit, which provide the gate bias for the switching transistor driving the inductor. The current drain, I_{O1} , varies with the load and is typically $10\mu A$. The current, I_{O2} , through the internal resistors R_1 and R_2 , is typically $1\mu A$.

S1F76330 Series Built-in Crystal Oscillator Type CMOS Switching Regulators

DESCRIPTION

The S1F76330 series of CMOS switching regulators provide input voltage step-up and regulation to a specified voltage using an external coil. The devices in these series incorporate precision, low-power reference voltage generators and transistors for driving an internal comparator. They feature low power consumption, low operating voltages and standby operation.

The devices offer a range of fixed output voltages, from 2.35 to 5.00V.

They are available in 8-pin SOP3s.

APPLICATIONS

- Fixed-voltage power supplies for battery-operated equipment such as portable video cassette recorders, video cameras and radios
- Power supplies for pages, memory cards, calculators and similar hand-held equipment
- Fixed-voltage power supplies for medical equipment
- Fixed-voltage power for communications equipment
- Power supplies for microcomputers
- Uninterruptable power supplies

FEATURES

- 0.9V (Min.) operating voltage
- 8 μ A (Typ.) maximum current consumption
- Standby operation
- 3 μ A (Typ.) standby current consumption
- Built-in oscillator circuit for use with external crystal oscillator
- SOP3-8pin

PACKAGE MARKINGS

S1F76330 device packages use the following marking.

FUNCTIONAL DESCRIPTIONS

Basic Voltage Booster Operation

Tr1 switches ON and OFF at the frequency of the clock pulses from the crystal oscillator. When the transistor is ON, the circuit stores energy in L. When it is OFF, this energy flows through D to charge C.

Internal Circuits

Crystal oscillator

The S1F76330 series incorporate a crystal oscillator circuit. An external crystal and drain resistor are used to generate the booster circuit clock. The crystal oscillator is connected to CI and CO as shown in the following figure.

In the S1F76330 series, the crystal oscillator output is sent to CLO as the VO system signal. The crystal oscillator circuit is activated by VI but, because the output level is shifted and the output is connected to CLO, the oscillator output cannot be obtained without a voltage at VO. Since the crystal oscillator is activated when an input voltage is applied, oscillation continues even in standby mode.

Reference voltage generator and output voltage regulator

The reference voltage generator regulates V11 to generate a voltage for the voltage regulator circuit.

The output voltage regulator regulates the boosted output voltage. This voltage is determined by the level at point A between the two resistors connecting VO and GND. These series use an on-chip resistor to set the output at a specified voltage.

Note

In step-up voltage operation, the ripple voltage created by the switching operation is large relative to the output voltage described above. This ripple voltage is affected by external components and load conditions. The user is advised to check this voltage carefully.

Standby mode

Connecting \overline{PS} to GND places the chip in standby mode. In this mode, the crystal oscillator is disabled, switching off the inductor drive transistor and the voltage booster circuit. Typically, \overline{PS} is connected to \overline{RST} . If standby mode is not required, leave \overline{PS} open as it has a pull-up resistor.

Output voltage response compensation

The S1F76340 series incorporates a response compensation input. A response compensation capacitor is connected between VCONT and VO, allowing the ripple voltage generated by the boosted output voltage to be suppressed to a minimum.

S1F76300 Series

Powering up

Ensure that V_O is at least the minimum operating voltage (0.9V) before switching on the booster circuit. One way to do this is to connect a capacitor between \overline{PS} and GND so that the chip connects V_O to V_I when the power is applied for the first time.

TYPICAL APPLICATIONS

Example Circuits

The output current, I_O , and power conversion efficiency Pe_{ff} , of a particular device in the series depends on fac-

tors such as the switching frequency, type of coil, and the size and type of other external components.

- $Pe_{ff} = 75\%$ when $L = 220\mu\text{H}$ (drum coil), $V_{II} = 1.5\text{V}$, $f_{CLK} = 32\text{kHz}$, $I_O = 9\text{mA}$
- $Pe_{ff} = 80\%$ when $L = 300\mu\text{H}$ (toroidal coil), $V_{II} = 1.5\text{V}$, $f_{CLK} = 32\text{kHz}$, $I_O = 10\text{mA}$

External Components

The performance characteristics of switching regulators depend greatly on the choice of external components. Observing the following guidelines will ensure high performance and maximum efficiency.

Inductor

Use an inductor with low direct-current resistance and low losses.

Leadless

Pre-wound, leadless inductors using surface-mount technology are the most suitable for portable equipment and other space-critical applications.

Drum coil

Avoid drum coils because their magnetic field can induce noise.

Toroidal coil

Use a toroidal coil to virtually eliminate magnetic field leakage, reduce losses and improve performance.

Diode

Use a Schottky barrier diode with a high switching speed and low forward voltage drop, V_F .

Capacitor

To minimize ripple voltages, use capacitors with a small equivalent direct-current resistance for smoothing.

Other Applications

Voltage booster

Combining an S1F76330M1B0 switching regulator with an S1F76610C/M DC/DC converter and voltage

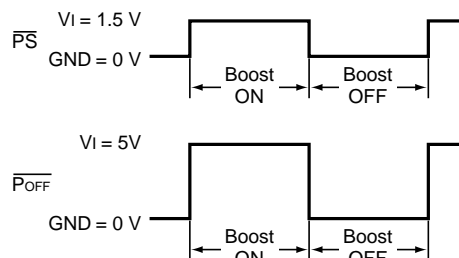

regulator creates the voltage booster circuit shown in the following figure.

Potential levels are shown in the following figure.

Although the circuit appears to have two ON/OFF control points, \overline{PS} on the S1F76330M1B0 and \overline{POFF} on the S1F76610C/M, \overline{PS} only shuts down the S1F76330M1B0. The input voltage still reaches the S1F76610C/M through L and D.

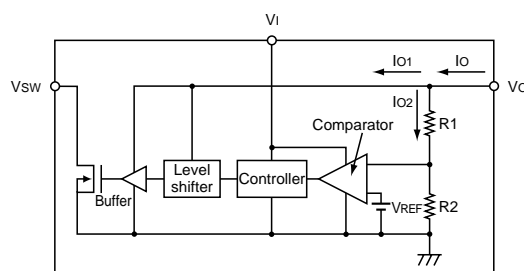

Output voltage adjustment

To ensure stable output, any circuit that adjusts the output voltage must contain $C1$, R_A and R_B . To stop switching current from affecting V_O , the circuit must also satisfy the condition $I_O < I_R$.

The following figure summarizes the relevant circuits inside an S1F70000 series chip.

V_O is connected to the level shift and buffer circuit, which provide the gate bias for the switching transistor driving the inductor. The current drain I_{O1} , varies with the load and is typically $10\mu A$. The current, I_{O2} , through the internal resistors $R1$ and $R2$ is typically $1\mu A$.

S1F71100 Series PWM Type Step-down DC/DC Switching Regulator

DESCRIPTION

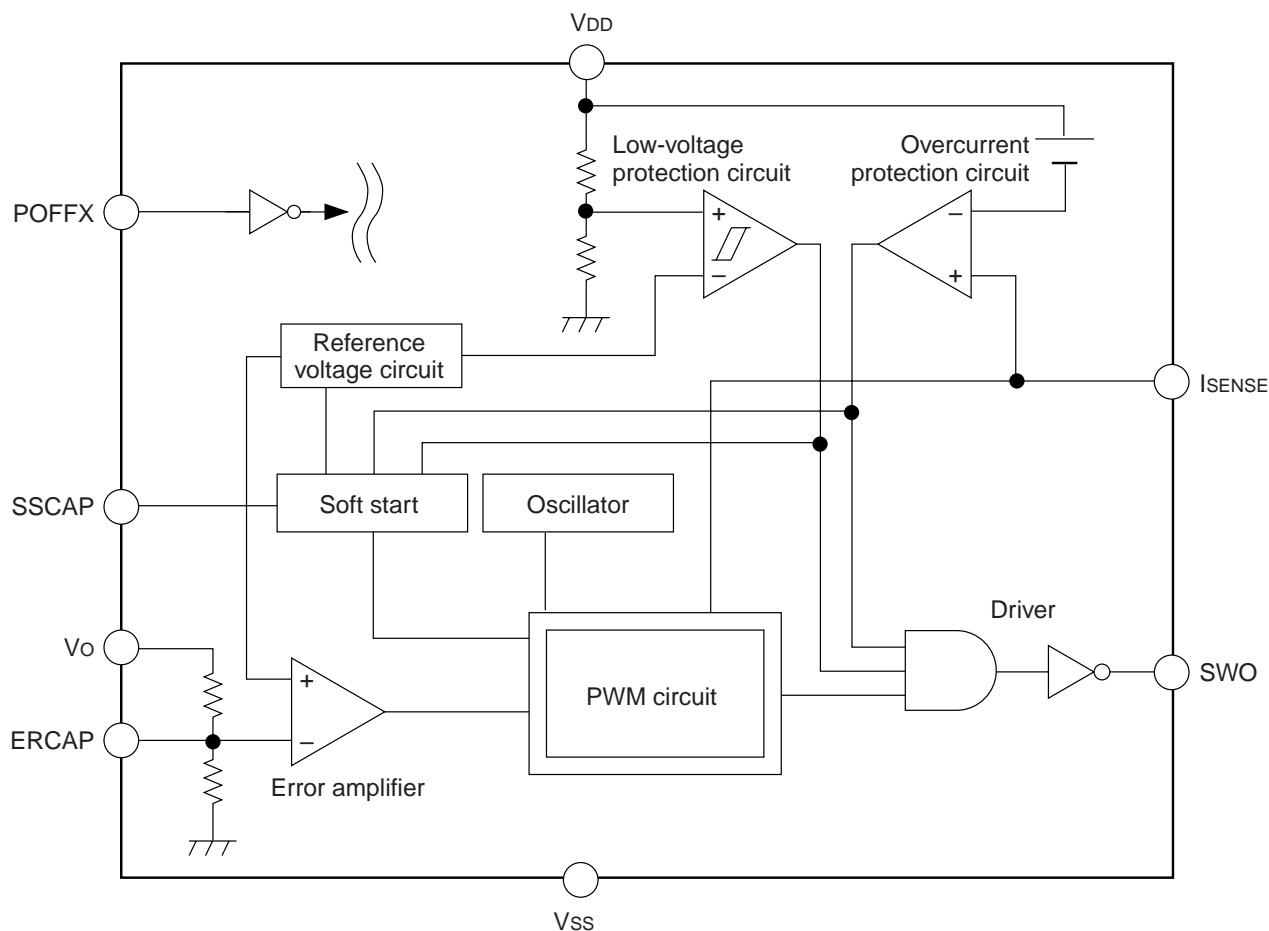

S1F71100 is a pulse width modulation (PWM) type step-down DC/DC converter control IC for which the CMOS process is used and to which a power transistor is connected outside. S1F71100 is composed of an oscillator, a reference voltage circuit, an error amplifier, a PWM circuit, a soft start circuit, a driver, etc. When this IC drives an external P ch power MOS transistor, S1F71100 can constitute a step-down DC/DC converter that converts input voltages up to 12V into the output voltage of 3.3V.

S1F71100 is also provided with a low-voltage protection circuit, an overcurrent protection circuit and a soft start protection circuit. When receiving external signals, S1F71100 can stop the oscillator and the switching circuit and turn off the power, so that it can reduce wasteful current consumption at the time of system halt.

FEATURES

- Input voltage : 3.3V ~ 12V
 - Output voltage : 3.3V (S1F71100M0A0)
 - Power off current : 1 μ A
 - Self current consumption : 800 μ A
 - Frequency fixing (200kHz) PWM
 - Power off function (IC shutdown)
 - Soft start function
 - Overcurrent protection function
 - Low-voltage protection function
 - Shipping pattern : plastic package SOP4-8pin
- * Radiation-resistant design has not been provided for this specification.

8	Vss	Power supply	Power supply pin (—)

FUNCTIONAL DESCRIPTIONS

Description of Operation

S1F71100 is a step-down switching regulator control IC of load current detection type pulse width modulation (PWM) system and is composed of an oscillator, a reference voltage circuit, an error amplifier, a PWM circuit, various protection circuits, etc.

S1F71100 can constitute a switching regulator, which converts input voltages up to 12V into output voltages of 3.3V, when external parts such as a power MOSFET, a diode, an inductor and a capacitor are connected to it. S1F71100 controls PWM by means of the two systems of output voltage feedback and load current feedback. The output voltage feedback system converts output voltage values of the switching regulator into voltage feedback signals through the error amplifier. And the load current feedback system detects currents flown to the external load current detection resistor as voltage values at the load current detection pin and converts them into current feedback signal in the internal circuit. These two feedback signals control the switching duty so that outputs from the switching regulator become optimum all the time. When the output voltage reduces, the output level of the error amplifier changes, and the switching duty is controlled so that the switching on duty of the output transistor increases.

Oscillator

Since S1F71100 has a built-in oscillator, and no external part is necessary. The oscillation frequency is fixed to 200kHz (Typ.). The oscillator stops its operation when the power is turned off. When the low-voltage protection circuit detects a low voltage, the output transistor is turned off, but the oscillation continues inside the IC.

Soft Start

When a capacitor is connected to the SSCAP pin, S1F71100 can set a soft start operation to prevent inrush current at the time when the power is turned on. (Figure 6-1) The SSCAP pin is at the VSS level when the power is turned off. When the soft start operation begins, the soft start capacitor starts being charged and the voltage at the SSCAP pin rises slowly. The output voltage rises gradually as the voltage at the SSCAP pin rises. This operation controls the switching pulse width at the time when the power is turned on and restrains surge current and output overshoot. The soft start time can be set according to the capacitance value of a capacitor to be

connected.

The voltage at the SSCAP pin drops to the VSS level when an overcurrent is detected, when a low voltage is detected or when the power is turned off, and the soft start operation begins.

Figure 6.1 Connection Diagram of SSCAP Pin

Low-voltage Protection Circuit

The low-voltage protection circuit monitors the supply voltage (voltage at the VDD pin). When the supply voltage drops below a detected voltage value, the low-voltage protection circuit works and stops the switching operation of the output transistor. This low-voltage protection circuit links to the soft start circuit and drops the voltage at the SSCAP pin to the VSS level during detection of low voltage.

The low-voltage protection circuit has hysteresis. When the supply voltage returns to more than the release voltage, the voltage at the SSCAP pin rises slowly and the soft start circuit starts its operation, then the low-voltage protection circuit resumes the switching operation.

Overcurrent Protection Circuit

When the current flowing through the current detection resistor increases more than the set current value and the voltage at the ISENSE pin drops below a detected voltage value, the overcurrent protection circuit operates. When the overcurrent protection circuit operates, it maintains the SWO pin at the VDD level and turns off the output transistor. It links to the soft start circuit, and the soft start circuit controls output voltage rise after detection of overcurrent.

Power Off Function

S1F71100 can control circuit operations according to external signal control. When the POFFX pin is connected to the VSS level, all circuits stop their operations and their powers are turned off. The current consumption at the power off state is less than 1μA. When the power is off, the SWO pin is at the VDD level and turns off the voltage transistor. The voltage at the SSCAP pin

comes to the VSS level, and the output voltage is controlled with the soft start circuit after the power off state is released. In the operating state, set the POFFX pin to the VDD level to operate it. The POFFX pin cannot be operated in an open state. When the power off function is not used, connect the POFFX pin to the VDD pin.

S1F71200 Series PWM Type Step-up/down DC/DC Switching Regulator

DESCRIPTION

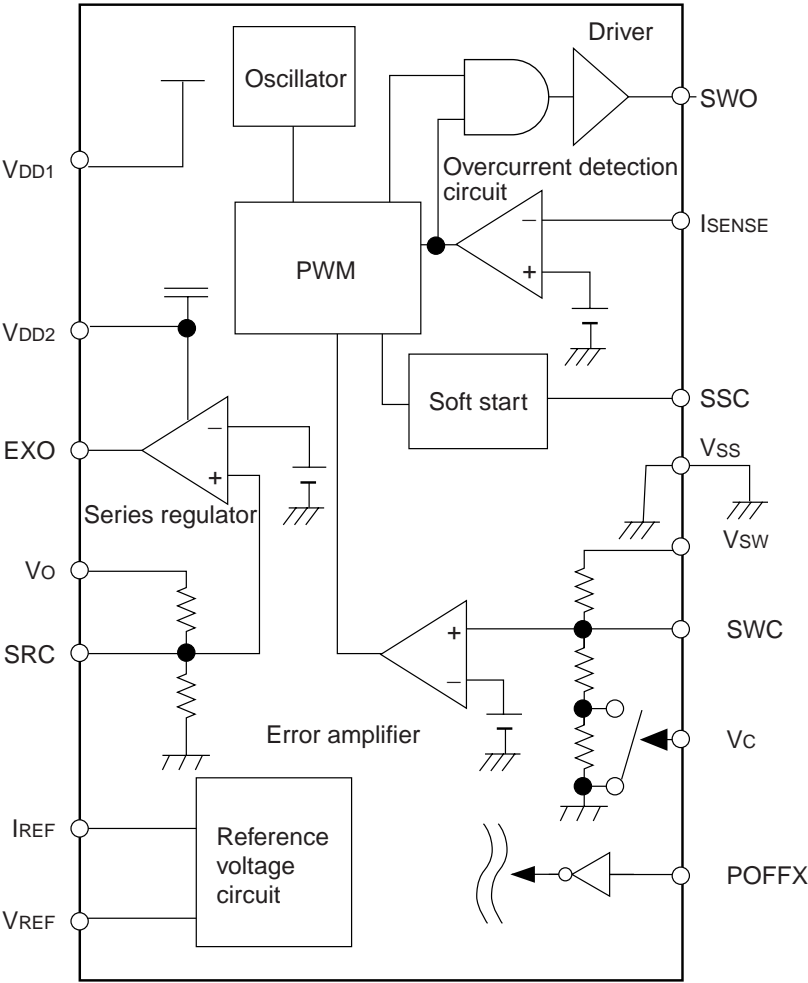

S1F71200 is a step-up/step-down DC/DC converter control IC for which the CMOS process is used and to which a power transistor is connected outside. S1F71200 is composed of an oscillator, a reference voltage circuit, an error amplifier, a PWM circuit, a series regulator, a driver, etc. When this IC drives an external power transistor, S1F71200 can constitute a step-up/step-down DC/DC converter that operates as a [step-down] series regulator when the input voltage is High and that operates as a [step-up] switching regulator of pulse width modulation system (PWM) when the input voltage is Low.

S1F71200 is also provided with an overcurrent protection circuit and a soft start circuit. When receiving external signals, S1F71200 can stop the oscillator and the switching circuit and turn off the power, so that it can reduce wasteful current consumption at the time of system halt.

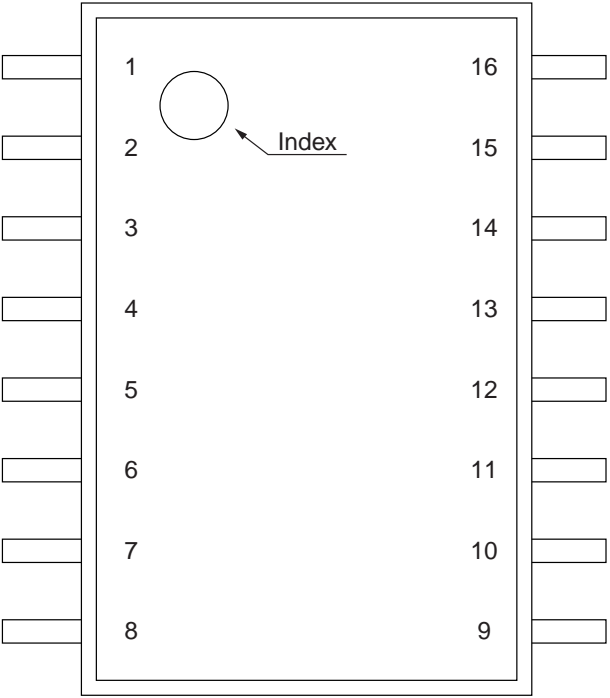

FEATURES

- Input voltage : 2.5V to 12.0V
- Output voltage : 5.0V (S1F71200M0A0)
3.3V (S1F71200M0B0)
- Power off current : 1.0μA
- Self current consumption : 150μA
(step-up portion)
15μA
(step-down portion)
- Frequency fixing (200kHz) PWM at step-up time
- Power off function (IC shutdown)
- Soft start function
- Overcurrent protection function
- Shipping pattern : plastic package
(SSOP2-16 pin)
- * Radiation-resistant design has not been provided for this specification.

15	ISENSE	Input	VDD1	Overcurrent detection pin
16	SWO	Output	VDD1	Step-up switching power transistor drive pin

FUNCTIONAL DESCRIPTIONS

Description of Operation

S1F71200 is a switching regulator (step-up) and series regulator (step-down) control IC of pulse width modulation (PWM) system. When external parts such as transistor, inductor, capacitor, diode and resistor are connected, S1F71200 can constitute a step-up/step-down DC/DC converter.

When the input voltage is lower than the specified voltage value, S1F71200 raises the voltage to the set voltage (selectable at the VC pin) with the switching regulator and lowers the step-up voltage with the series regulator to stabilize the output voltage. On the other hand, when the input voltage is higher than the specified voltage value, S1F71200 stops the operation of the switching regulator (step-up) and operates the series regulator (step-down) only. Switching operations with input voltage makes constant voltage outputs possible all the time.

Operation of Switching Regulator

S1F71200 monitors voltage at the Vsw pin, i.e., the output voltage of the step-up switching regulator, and controls pulse width of the switching transistor. When the voltage at the Vsw pin drops below the step-up set voltage, S1F71200 changes the output level of the error amplifier and increases the on duty of the switching transistor for control.

On the other hand, when the voltage at the Vsw pin rises over the step-up set voltage, S1F71200 reduces the on duty for control. When voltages higher than the step-up set voltage is constantly supplied to the Vsw pin, S1F71200 stops operation of the step-up switching. When the switching stops completely, the input voltage is supplied to the Vsw pin through the coil and the diode. (The voltage at the Vsw pin comes to the one obtained by reducing V_F of the diode from the input voltage.)

Step-up Set Voltage

Step-up set voltage can be selected at the VC pin.

- ① VC = High VDD1 level :
Step-up set voltage = 6.0V (S1F71200M0A0)
4.3V (S1F71200M0B0)
- ② VC = Low VSS level :
Step-up set voltage = 5.5V (S1F71200M0A0)
3.8V (S1F71200M0B0)

In case of output stability and heavy load like ripple, ① is superior, but for the conversion efficiency at step-up operation, ② is superior. Characteristics vary with applicable external parts or voltage and load conditions. So, select a proper voltage after sufficient evaluation. The VC pin cannot be used in the open state.

Soft Start

When a capacitor is connected to the SSCAP pin, S1F71200 can set a soft start operation to prevent inrush current at the time when the power is turned on. The SSCAP pin is at the VSS level when the power is turned off (POFFX=VSS). When the operation state is set (POFFX=VDD1), the soft start capacitor starts being charged and the voltage at the SSCAP pin rises slowly. The step-up output voltage rises gradually as the voltage at the SSCAP pin rises. This operation is carried out when the power is turned on, when the power off is released or when the overcurrent detection is released and restrains surge current and output overshoot.

Overcurrent Protection Circuit

The overcurrent protection circuit functions when an overcurrent flows through the current detection resistor during the step-up operation and the voltage at the ISENSE pin rises over the set voltage value. When the overcurrent protection function works, the transistor drive pin SWO comes to the VSS level and the switching transistor is turned off. Since the overcurrent protection circuit links to the soft start circuit, it drops the voltage at the SSCAP pin to the VSS level during overcurrent detection. When the overcurrent detection is released, the voltage at the SSCAP pin rises slowly and the soft start operation starts.

Power lost at the current detection resistor becomes a factor of lower efficiency. When the overcurrent protection circuit is not necessary, short-circuit the ISENSE pin to the VSS pin. The ISENSE pin cannot be used in an open state.

Operation of Series Regulator

S1F71200 has a built-in series regulator control circuit. When driving the PNP transistor as an external part, S1F71200 reduces voltage supplied to the VDD2 pin and constitutes a series regulator. The VDD2 pin is generally connected to the VSW pin of step-up output.

This series regulator operates monitoring voltage at the VO pin of step-up/step-down output. It controls the drive current (base current of the PNP transistor) at the EXO pin to stabilize voltage at the VO pin.

Power Off Function

S1F71200 can control circuit operations according to external signal control. When the POFFX pin is set to the VSS level, all circuits stop and their powers are turned off. The current consumption at the power off state is less than 1μA. When the power is off, the SWO pin is set to the VDD level, the EXO pin is set to the VDD2 level and respective external transistors are turned.

The voltage at the SSCAP pin comes to the VSS level, and the soft start circuit controls the step-up operation output voltage is controlled with the soft start circuit after the power off state is released. The soft start circuit controls step-up operations after power off release. When being set to the VDD level, the POFFX pin operates in general. The POFFX pin cannot be used in an open state. When the power off function is not used, connect the POFFX pin to the VDD1 pin.

5. DC/DC Switching Regulators & Voltage Follower

S1F75300 Series Step-up Switching Regulator With Built-in Voltage Follower

DESCRIPTION

S1F75300 is a highly efficient and low power consumption step-up switching regulator with built-in voltage follower developed by using CMOS silicon gate processor. (For boosting, the external coil is used.)

The output voltage is adjustable with the 8-bit electronic volume.

This IC is optimum to power supply portions of medium and small liquid crystal panels for which high efficiency is requested.

FEATURES

- Boosting efficiency : 80%
- Low current consumption : Typ.200μA (without load)
- Output voltage (step-up output) : 30V Max., adjustable with the electronic volume.
- Optimum to small and medium liquid crystal panels
Input voltage : 2.7V to 5.5V
Output voltage : to 27V
- Reduction of current consumption at the time of standby with power-off function

FUNCTIONAL DESCRIPTIONS

Switching Regulator Portion

Operation of Basic Boosting Circuit

S1F75300 boosts using clock pulses generated in the PWM control circuit. Figure 3 shows the block diagram for explaining the principle of operation of the boosting circuit. This circuit stores energy in the inductance L when the switching transistor ($Tr1$) is on and can charge the capacitor C with the stored energy by passing it through the diode D for output when the switching transistor is off.

Figure 3 Block Diagram of Boosting Circuit

Reference Voltage Generator, Output Voltage Setting Stabilizing Circuit

- Reference Voltage Generator, Output Voltage Setting Stabilizing Circuit

The reference voltage generator is for generating stabilized voltage (reference voltage) not depending on input voltage necessary for the output voltage setting stabilizing circuit or the voltage detection circuit.

The reference voltage generator has a built-in temperature characteristic compensation circuit. For the temperature characteristic, any one temperature characteristics can be selected out of four temperature characteristics in the range from $-0.18\%/^{\circ}\text{C}$ to $-0.06\%/^{\circ}\text{C}$. (Selection with Mask Option.)

The output voltage setting stabilizing circuit outputs the stabilized voltage VO_2 after receiving a boosted voltage. The output voltage VO_2 can be set to a specified voltage when the position of Point A on the intermediate tap of the resistor connected between the pin VO_2 and the pin GND as shown in Figure 4 is changed.

The variable resistor in Figure 4 has the function of electronic volume and can change the output VO_2 as the resistance value is changed as mentioned in Paragraph 5.1.3.

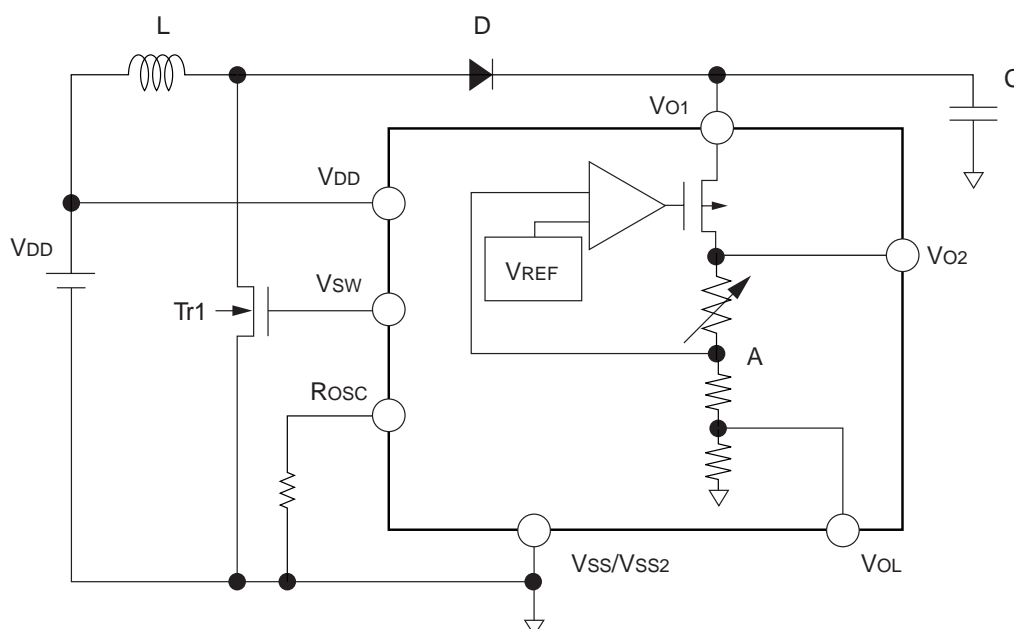

Figure 4 Stabilizing Circuit

Note

In the practical boosting state, a ripple voltage is superimposing the output setting voltage set as mentioned above. Since this ripple voltage is affected by applicable external parts and loading conditions, set the value of the coil through which the load current passes and check it before use.

- Output Voltage External Adjustment Pin (VOL)

The voltage VO_2 boosted and stabilized with the output voltage setting stabilizing circuit can slightly adjust output voltages when an external resistor is connected to the output voltage external adjustment pin VOL as shown in Figure 10 in Chapter 7, Example of External Connection.

Electronic Volume Portion

S1F75300 has a built-in 8-bit shift register and a built-in 8-bit latch so that it can vary the voltage VO2 when serial data is input. The 8-bit latch enables to vary the output voltage VO2. Data taken in the shift register is taken in the 8-bit latch as a synchronous strobe is input. The following shows the block diagram and the timing chart.

DATA : Serial data input pin for setting output voltage and bias value.

"Data 1" is input at the High level and "Data 0" is input at the Low level. Data are input to (LSB) and (MSB) in this order.

CLK : Clock input to shift register pin

When the clock starts, data at the DATA pin is taken in the shift register. Data to be taken in shift one after another for every clock. So, data input last becomes valid.

LATCH : Latch signal input pin

When latch signal is set to High the content of the shift register is taken in the 8-bit latch.

Voltage Follower Portion

The voltage follower portion of S1F75300 enables to adjust bias with the electronic volume as explained in Paragraph 5.1.3.

Figure 6 shows the block diagram of the voltage follower portion.

After the power is turned on, the resistance between V2 and V3 is set to nR . (The n value is selected optionally.) When n is 11 and 13 for example, the voltages at V1 to V4 are as follows after the power is turned on:

Table 2 Output Voltage of Voltage Follower

	n=11 (1/160 duty)	n=13 (1/240 duty)
V1	$13/14 \cdot V_0$	$16/17 \cdot V_0$
V2	$12/14 \cdot V_0$	$16/17 \cdot V_0$
V3	$2/14 \cdot V_0$	$2/17 \cdot V_0$
V4	$1/14 \cdot V_0$	$1/17 \cdot V_0$

Figure 6 Block Diagram of Voltage Follower

EN Pin

This pin is for boosting action and for stopping and starting the voltage follower portion.

When the EN pin is set to Low level, the internal circuit action stops and the current consumption is restrained.

6. Voltage Detector

S1F77200Y Series CMOS Voltage Detectors

DESCRIPTION

The S1F77200Y series products are non-adjusting voltage detectors being developed utilizing the base of the CMOS silicon gate process.

This voltage detector consists of the reference voltage circuit, voltage comparator, hysteresis circuit and output circuit, all operating on smaller current.

A voltage range to be detected is internally set on respective detectors. A wide variety of our standard products are grouped as shown below according to the output format employed for the voltage detector output pin. The S1F77200Y series employs N-channel open drain output approach. And the S1F77210Y series and S1F77220Y series employ the CMOS output and P-channel output, respectively.

The package used is the SOT89-3 pin plastic package. Our voltage detectors are used for determining battery life, and also for monitoring supply voltage fed to microcomputers and LSI systems.

FEATURES

- Full lineups: 19 types are prepared for the detection range between 2.0V to 5.0V.
For the detection range from 0.8V to 2.5V, 7 types are available (products designed for lower voltage detection).
- Low operating current: Typ. 2.0 μ A ($V_{DD} = 5.0V$).
- Low operating voltage: 1.5V at minimum.
- Absolute maximum rated voltage: 15V maximum.
- Highly stable built-in reference voltage source: Typ. 1.0V.
- Better temperature characteristics of output voltage: Typ. -100ppm/ $^{\circ}$ C.

2	VDD	Input voltage pin (positive side)
3	VSS	Input voltage pin (negative side)

PIN ASSIGNMENTS

FUNCTIONAL DESCRIPTIONS

The S1F77200Y series has the circuit configuration as shown in the figure below. For the detection, divided potential (V_{REG}) across the resistors inserted across the power supply and the reference voltage (V_{REF}) generated on the IC are entered to the voltage comparator. Since the voltage comparator is designed to detect a target voltage even when potential difference between V_{REG} and V_{ref} minute, hysteresis is added so that the comparator may not fail due to noise on the power supply and such. In the example shown in the figure below,

detection voltage (V_{DET}) for the input voltage drop and relief voltage (V_{REL}) for the increased input voltage are set based the following formula.

$$\text{Detection voltage: } V_{DET} = \frac{R1+R2+R3}{R2+R3} \cdot V_{REF}$$

$$\text{Relief voltage: } V_{REL} = \frac{R1+R2+R3}{R3} \cdot V_{REF}$$

The following figures show the input and output characteristics of the S1F77200Y series.

[S1F772*0Y1*0 Type]

S1F772*0Y2*0 Type

Note: The above input/output characteristics assumes that the pull up resistor is connected to the output pin for the S1F77200Y series. For the S1F77220 series, it assumes that the pull down resistor is connected between the OUT and VDD pins.

If the input voltage that is applied between VDD and VSS terminals drops below the lower limit of voltage for IC operation, the output condition of the OUT terminal may become unsteady.

Ensure to prevent problems from occurring in circuit operation.

ABSOLUTE MAXIMUM RATINGS

Parameter	Symbol	Rating	Unit

EXAMPLES OF EXTERNAL CONNECTION

SAMPLE CIRCUITS (S1F77210Y Series)

CR timer circuit

When the S1F77210Y circuit configured as shown in Figure 5-14, it can be used as a CR timer circuit.

Figure 5-14 CR timer circuit

Battery backup circuit

The following is an example of the supply voltage switching circuit for the battery backup supply configured featuring the S1F77210Y series.

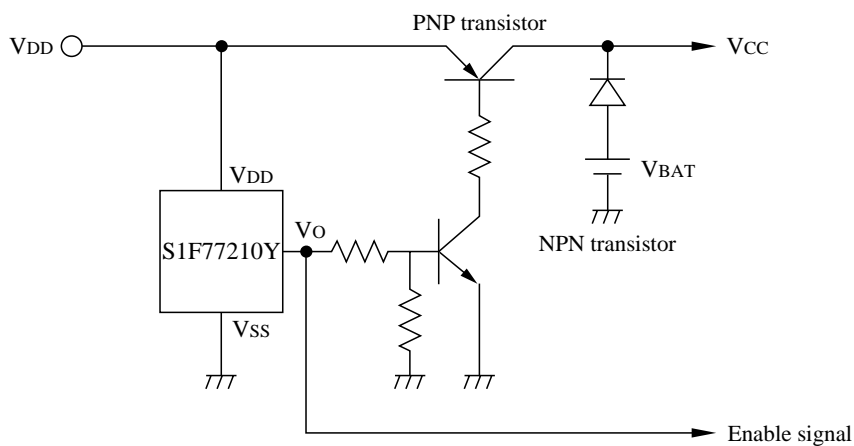

Figure 5-15 Battery backup circuit

SAMPLE CIRCUITS (S1F77200Y Series)

CR timer circuit

When the S1F77200Y circuit is configured as shown in Figure 5-16, it can be used as a CR timer circuit.

Figure 5-16 CR timer circuit

Battery backup circuit

The following is an example of the supply voltage switching circuit for the battery backup configured featuring the S1F77200Y series.

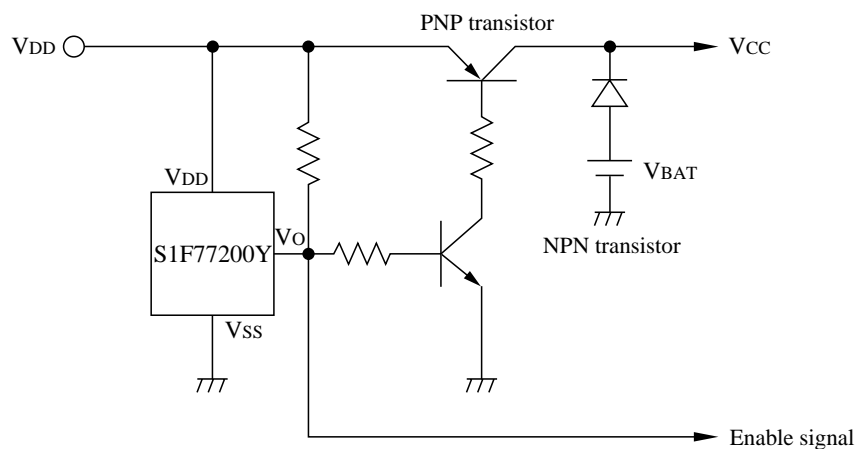

Figure 5-17 Battery backup circuit

PRECAUTIONS

Short cut current on the S1F77210 (CMOS output voltage detector)

Since the S1F77200Y series employs CMOS output, as an input voltage nears the detection voltage range, short cut current is flown between VDD and VSS. The short cut current is voltage sensitive, and approximately 2 mA flows at 5V level or so (our products are not check for short cut current after volume production has been started).

Although duration of the short cut current depends on operating conditions (such as type the circuit used and supply impedance), normally it is assumed to continue several usec to several dozens of usec.

If a load with high impedance is inserted across the power supply, oscillation can be introduced by the short cut current. In order to reject this trouble, the following measures should be considered:

- (1) Reduce the resistance value.
- (2) Insert a capacitor.
- (3) Replace with the S1F77200Y series (it employs N-channel open drain approach).

7. Appendix

ABSOLUTE MAXIMUM RATINGS

Absolute maximum ratings are the maximum physical and electrical ratings of a device beyond which performance degradation or damage will occur. Always check circuit conditions before using a device to avoid exceeding these ratings. Typically, absolute maximum ratings include the following parameters.

1. Power supply voltage

Steady state applied voltages, noise, reverse voltage transients and power-on-transients can degrade or damage the integrated circuit if they exceed the maximum power supply voltage rating.

2. Input signal voltage

Input signals exceeding this rate can damage input protection circuits

3. Output current

Generally, specifications are not set for CMOS devices with small output currents. Devices that provide large drive currents will have output current specifications.

4. Power dissipation

The maximum power dissipation of a device is limited by its construction and package type. Maximum output current limits are set to prevent thermal damage.

5. Operating temperature range

The temperature range for normal device operation with no change in performance characteristics.

6. Storage temperature range

The temperature range for device storage with no degradation or damage. This specification is particularly important when ICs are being transported by air.

7. Soldering temperature and the duration

The maximum soldering temperature and the time for which the leads can be at this temperature.

RECOMMENDED OPERATING CONDITIONS

Recommended operating conditions are the conditions under which a device functions correctly. These include power supply voltage, input conditions and output current. These conditions are sometimes listed as part of the electrical characteristics.

ELECTRICAL CHARACTERISTICS

Electrical characteristics specify the DC and AC characteristics of a device under the worst measurement conditions.

POWER DISSIPATION CONDITIONS

To prevent damage always consider the following points when designing with power regulation ICs.

1. A precise thermal design is necessary to ensure adequate heat dissipation.

The following figure shows the power dissipation capacity in relation to ambient temperature.

The following figure shows the cost and reliability of a product and is significant when designing a system.

Appendix

The following figure shows a thermal design model which can be used to determine heatsink capacity.

2. Ensure that the regulator common pin is a single-point ground to prevent earth loops. Make ground lines as thick and short as possible. Use the specified bypass capacitors for inputs and outputs. If there is a switching load, use a tantalum or ceramic capacitor, as these devices have a high frequency response between the power supply and ground.

PARAMETER SUMMARY

Symbol	Parameter
C _D	Drain capacitance
C _{F8}	Field slew capacitance
C _G	Gate capacitance
C _I	Input capacitance
C _n	Capacitance
CT	Crosstalk
C _{Tn}	Temperature gradient
f _{CLK}	Clock frequency
f _{max}	Maximum clock frequency
f _{OSC}	Oscillator frequency
FT	Field through (channel OFF)
I _{BSQ}	Backup switching leakage current
I _{DDO}	Operating current
I _{DDS}	Standby current
I _{DD}	Power supply current
I _{IH}	High-level input current
I _{IL}	Low-level input current
I _{LK1}	input leakage current
I _{MAX}	Maximum current
I _O	Output current
I _{OH}	High-level output current
I _{OL}	Low-level output current
I _{OPR1}	Multiplier circuit power dissipation

Symbol	Parameter
I _{OPR2}	Stabilization circuit power dissipation
I _Q	Quiescent current
I _R	Reverse current
I _{SWQ}	Switching transistor leakage current
K _I	Output voltage temperature gradient
P _D	Power dissipation
P _{eff}	Voltage multiplication efficiency
R _{BSON}	Backup switch ON resistance
R _L	Load resistance
R _O	Output impedance
R _{ON}	ON resistance
R _{OSC}	Oscillator network resistor
R _{RV}	Stabilization voltage sensing resistor
R _{RVn}	Reference voltage
R _{SAT}	Stabilization output saturation resistance
R _{SWON}	Switching transistor ON resistance
T _a	Ambient temperature
t _{AE}	Minimum pulsewidth
t _{HA}	Address hold time
t _{HD}	Data hold time
THD	Total harmonic distortion
θ _{jn}	Thermal resistance
t _{MRR}	Memory reset recovery time

Symbol	Parameter
tMR	Memory reset
T _{opr}	Operating temperature
tPAE	Propagation delay
tPHL	Low-level transition time
tPLH	High-level transition time
tPLS	Propagation delay
tPOP	Propagation delay
tPS	Propagation delay
tSA	Address setup time
tSD	Data setup time
T _{sol}	Soldering temperature and time
T _{stg}	Storage temperature
V _{DD}	Power supply voltage
V _{DET}	Detection voltage
V _F	Forward voltage

Symbol	Parameter
V _I	Input voltage
V _{IH}	High-level input voltage
V _{IL}	Low-level input voltage
V _I	Input voltage
V _O	Output voltage
V _{off}	Input offset voltage
V _{op+}	Input voltage range
V _{OPMAX}	Maximum output voltage
V _{OPMIN}	Minimum output voltage
V _{REF}	Reference voltage
V _{REG}	Output voltage (regulated)
V _{SS}	Power supply voltage
V _{SSn}	Power supply voltage
V _{STA}	Oscillator start-up voltage
V _{STP}	Oscillator shut-down voltage

EMBOSS CARRIER TAPING STANDARD (SOT89-3pin)

TAPING INFORMATION

The emboss carrier taping standard is shown in the following table and figure. This standard conforms to

Dimension code	Dimensions/angles (mm/°)
A	5.0
B	4.6
D	1.5 +0.1, -0.05
E	1.50 ±0.1
F	5.65 ±0.05
P1	8.0 ±0.1
P0	4.0 ±0.1

the EIAJ RCI00B electronic parts taping specification. Each tape holds 1,000 devices.

Dimension code	Dimensions/angles (mm/°)
P2	2.0 ±0.05
T	0.3
T2	2.3
W	12.0 ±0.2
W1	9.5
θ	30°Max.

Note

The tape thickness is 0.1 mm Max.

There are no joints in either the cover or carrier tapes. Less than 0.2% of the total device count is comprised of non-sequential blanks. There are no sequential

blanks. This does not apply to the tape leader and trailer.

REEL SPECIFICATIONS

The reel specifications are shown in the following table and figure. The reel is made of paperboard.

Dimension code	Dimensions (mm)
A	178 ± 2.0
B	80 ± 1.0
C	13.0 ± 0.5
D	21.0 ± 1.0
E	2.0 ± 0.5
W	14.0 (See note.)
W1	1.5 ± 0.1
W2	17 (See note.)
r	1.0

Note

W and W2 are measured at the reel core.

DEVICE POSITIONING

Small molded power IC devices are positioned as shown in the following figure.

EMBOSS CARRIER TAPING STANDARD (SOP3-8pin)

TAPING INFORMATION

The emboss carrier taping standard is shown in the following table and figure. This standard conforms to

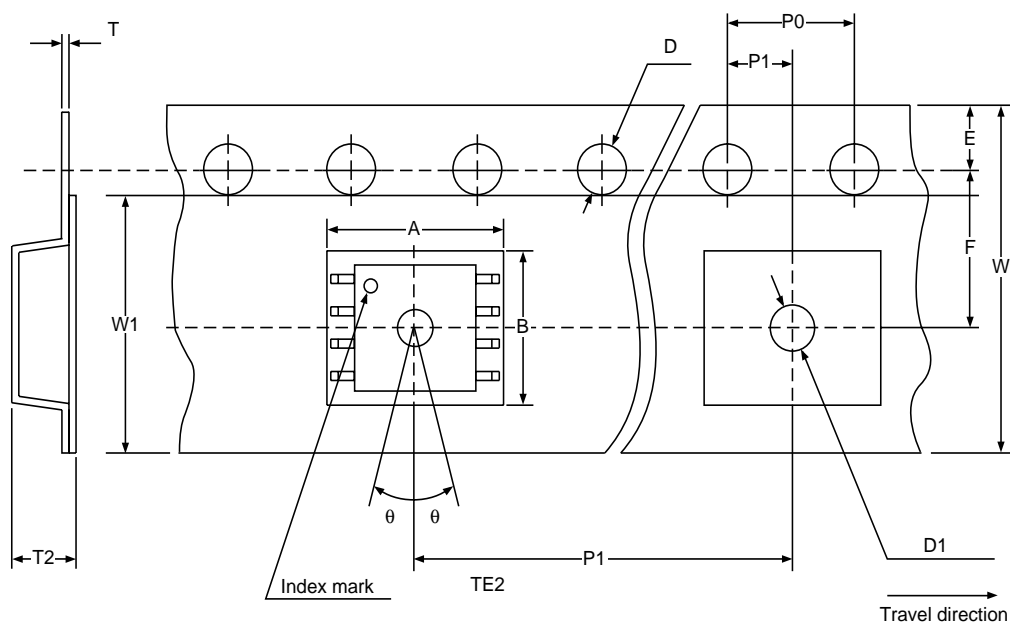

Dimension code	Dimensions/angles (mm/°)
A	6.7
B	5.4
D	1.55 +0.05, -0
D1	1.55 ±0.05
E	1.75 ±0.1
F	5.5 ±0.1
P1	8.0 ±0.1
P0	4.0 ±0.1

the EIAJ RCI009B electronic parts taping specification. Each tape holds 2,000 devices.

Dimension code	Dimensions/angles (mm/°)
P2	2.0 ±0.05
T	0.3 ±0.05
T2	2.5
W	12.0 ±0.3
W1	9.5
θ	15°Max.

Note

The tape thickness is 0.1 mm Max.

There are no joints in either the cover or carrier tapes. Less than 0.2% of the total device count is comprised of non-sequential blanks. There are no sequential

blanks. This does not apply to the tape leader and trailer.

REEL SPECIFICATIONS

The reel specifications are shown in the following table and figure. The reel is made of paperboard.

Dimension code	Dimensions (mm)
A	330 ± 2.0
B	80 ± 1.0
C	13.0 ± 0.5
D	21.0 ± 0.5
E	2.0 ± 0.5
W	15.4 ± 1.0 (See note.)
W1	2.0 ± 0.5
W2	23.4 (See note.)
r	1.0

Note

W and W2 are measured at the reel core.

DEVICE POSITIONING

Type B products are positioned so that the index mark is on the sprocket hole side of the tape, as shown in the following figure.

Appendix

Type F product are positioned so that the index mark is on the opposite side to the sprocket holes, as shown in the following figure.

EMBOSS CARRIER TAPING STANDARD (SOP5-14pin)

TAPING INFORMATION

The emboss carrier taping standard is shown in the following table and figure. This standard conforms to

Dimension code	Dimensions (mm/°)
A	8.4
B	10.6
D0	1.55 ± 0.05
D1	1.55 ± 0.05
E	1.75 ± 0.1
F	7.5 ± 0.1
P1	12 ± 0.1
P0	4.0 ± 0.1

the EIAJ RCI009B electronic parts taping specification. Each tape holds 2,000 devices.

Dimension code	Dimensions (mm/°)
P2	2.0 ± 0.1
T	0.3 ± 0.05
T2	3.0
W	16.0 ± 0.3
W1	13.5

Note

The tape thickness is 0.1 mm Max.

There are no joints in either the cover or carrier tapes. Less than 0.1% of the total device count is comprised of non-sequential blanks. There are no sequential

blanks. This does not apply to the tape leader and trailer.

Appendix

REEL SPECIFICATIONS

The reel specifications are shown in the following table and figure. The reel is made of paperboard.

Dimension code	Dimensions (mm)
A	330 ± 2.0
B	80 ± 1.0
C	13.0 ± 0.5
D	21.0 ± 1.0
E	2.0 ± 0.5
W	14.0 ± 1.5 (See note.)
W1	2.0 ± 0.5
W2	20.5 max (See note.)
r	1.0

Note

W and W2 are measured at the reel core.

DEVICE POSITIONING

Type B products are positioned so that the index mark is on the sprocket hole side of the tape, as shown in the following figure.

Type F products are positioned so that the index mark is on the opposite side to the sprocket holes, as shown in the following figure.

EMBOSS CARRIER TAPING STANDARD (SOP2-24pin)

TAPING INFORMATION

The emboss carrier taping standard is shown in the following table and figure. This standard conforms to

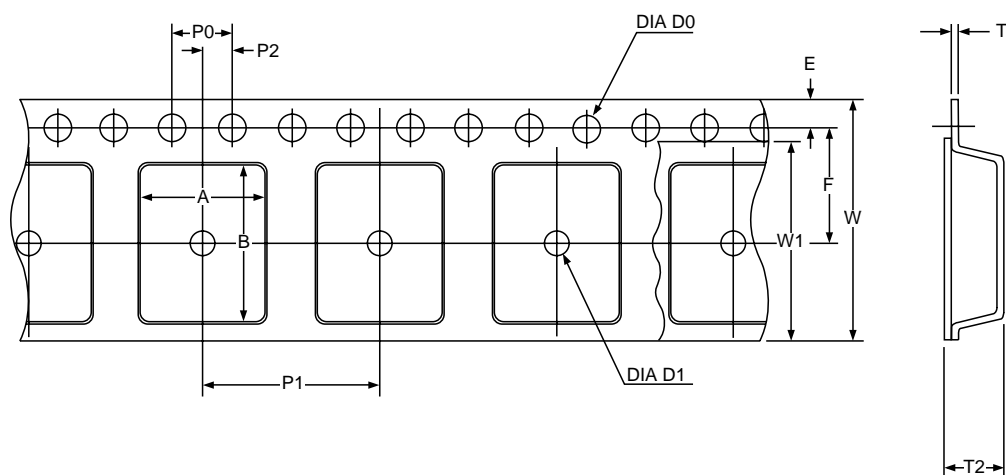

Dimension code	Dimensions (mm)
A	12.4
B	15.6
D0	1.55 +0.1, -0
D1	2.0 +0.1, -0
E	1.75 ±0.1
F	11.5 ±0.1
P1	16 ±0.1

the EIAJ RCI009B electronic parts taping specification. Each tape holds 1,000 devices.

Dimension code	Dimensions (mm)
P0	4.0 ±0.1
P2	2.0 ±0.1
T	0.3 ±0.05
T2	3.0 ±0.1
W	24 ±0.2
W1	21.5 Typ.

Note

The tape thickness is 0.1 mm Max.

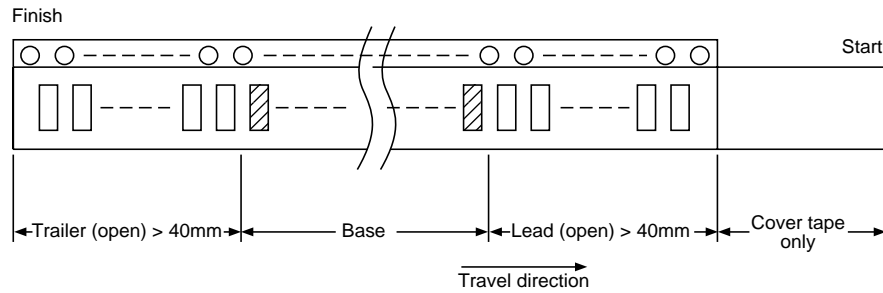

There are no joints in either the cover or carrier tapes. Less than 0.2% of the total device count is comprised of non-sequential blanks. There are no sequential blanks. This does not apply to the tape leader and

trailer. The tape tension should be approximately 10 N (1 kgf). A label indicates the part name, quantity and lot number.

Tape configuration

The tape configuration is shown in the following figure. Blank sections are provided as a leader and trailer, with 1,000 SOP2 packages fitted into the component mounting section between them. At the begin-

ning of the leader section there is an extra section of tape which contains the cover tape only.

[illegible][illegible]

Type F products are positioned so that the index mark is on the opposite side to the sprocket holes, as shown in the following figure.
