Shift Matrix

FEATURES

- Typical propagation delay: 1.9ns
- Typical supply current ($-I_{EE}$): 118mA

DESCRIPTION

The 100158 contains a combinatorial network which performs the function of an

8-bit Shift Matrix. Three control lines (S_n) are internally decoded to define the number of places which an 8-bit word, present at the inputs (D_n), is shifted to the right. The shifted word appears on the outputs Q_n . A Mode Control is provided which, if Low, forces Low all outputs to the left of the one that contains D_7 . This operation is sometimes referred to as low backfill. If M

is High, a circular shift is performed, such that D_0 appears at the output just to the left of the one that contains D_7 . This operation is commonly referred to as barrel shifting.

All unused inputs can be left open due to integrated pull-down resistors.

ABSOLUTE MAXIMUM RATINGS $V_{CC1} = V_{CC2} = \text{ground}$, $T_A = 0^{\circ}\text{C}$ to $+85^{\circ}\text{C}$ unless otherwise specified:

SYMBOL	PARAMETER	LIMITS	UNIT
V_{EE}	Supply voltage range	-7.0 to +0.5	V
V_{IN}	Input voltage (V_{IN} should never be more negative than V_{EE})	V_{EE} to +0.5	V
I_O	Output source current (continuous)	-55	mA
T_S	Storage temperature range	-65 to +150	$^{\circ}\text{C}$
T_J	Maximum junction temperature	+150	$^{\circ}\text{C}$

NOTE:
Operation beyond the limits set forth in this table may impair the useful life of the device.

NOTES:

- The specified limits represent the worst case values for the parameter. Since these worst case values normally occur at the supply voltage and temperature extremes, additional noise immunity can be achieved by decreasing the allowable operating condition ranges.
- Conditions for testing shown in the tables are not necessarily worst case. For worst case testing guidelines, refer to DC Testing, Chapter 1, Section 3.
- The specified limits shown in the DC electrical characteristics table can be met only after thermal equilibrium has been established. Thermal equilibrium is established by applying power for at least 2 minutes, while maintaining transverse airflow of 2.5 meters/sec (500 linear feet/min) over the device, mounted either in a test socket or on a printed circuit board. Test voltage values are given in the DC operating conditions table.
- The device can function down to $V_{EE} = -5.7V$, allowing operation with either the 10K or the 10KH family. Correction factors can be used to calculate new DC limits for the extended V_{EE} range. For more information, see Chapters 5 and 10, Section 4.
